### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

## ABSTRACT

The organization of nanowires on surfaces remains a major obstacle toward their large-scale integration into functional devices. Surface-material interactions have been used, with different

1  
2  
3 materials and substrates, to guide horizontal nanowires during their growth into well-organized  
4 assemblies, but the only guided nanowire heterostructures reported so far are axial and not radial.  
5  
6 Here we demonstrate the guided growth of horizontal core-shell nanowires, specifically of  
7  
8 ZnSe@ZnTe, with control over their crystal phase and crystallographic orientations. We exploit  
9  
10 the directional control of the guided growth for the parallel production of multiple radial p-n  
11  
12 heterojunctions, and probe their optoelectronic properties. The devices exhibit a rectifying  
13  
14 behavior with photovoltaic characteristics upon illumination. Guided nanowire heterostructures  
15  
16 enable the bottom-up assembly of complex semiconductor structures with controlled electronic  
17  
18 and optoelectronic properties.

27 Over the last two decades, single-crystal semiconducting nanowires (NWs) have been the  
28 focus of extensive and ongoing research.<sup>1, 2</sup> Their fundamental properties along with increasing  
29 control over their dimensions and composition provide a unique combination that is continuously  
30 exploited to explore physical phenomena and to test the potential use of nanowires as building  
31 blocks for various nanodevices, including electronics,<sup>3</sup> light-emitting diodes (LEDs),<sup>4</sup> lasers,<sup>5</sup>  
32 sensors<sup>6</sup> and energy-harvesting devices.<sup>7, 8</sup> Motivated by the prospect of unique properties,  
33 enormous efforts were invested in understanding the nuances of nanowire growth in order to  
34 ultimately gain control over their dimensions,<sup>9</sup> crystal structure,<sup>10</sup> composition,<sup>11</sup> and modulation  
35 of the latter.<sup>12</sup> Interfacing different materials to create nanowire heterostructures can result in  
36 electronic, photonic, magnetic, and thermal characteristics that are superior to their bulk or thin-  
37 film counterparts.<sup>13</sup> Moreover, their ability to relieve strain radially<sup>13</sup> while maintaining high  
38 crystallinity and the flexibility of their growth process enables the creation of unconventional  
39 material interfaces with high lattice mismatch.<sup>14</sup>

2  
3 Nanowire heterostructures, both axial and radial, are being investigated extensively for  
4 optoelectronic applications,<sup>15</sup> partly because they enable various degrees of freedom for band  
5 engineering. When considering radial heterostructures in particular, different configurations were  
6 tailored to fit specific requirements: For a high electron mobility system, a type I core-shell was  
7 designed to confine charge carriers in the core region while potentially reducing scattering from  
8 the nanowire surface.<sup>16</sup> For LEDs and lasers, multishell radial heterostructures act as confining  
9 layers<sup>17</sup> or gain medium<sup>18</sup> respectively. Radial heterostructures can also be engineered to embed  
10 single photon quantum emitters.<sup>19</sup> For photovoltaics, type II nanowire heterostructures<sup>20, 21</sup> are  
11 promising owing to the large interfacial area of the radial heterojunction, which results in  
12 efficient charge generation, separation and transportation.<sup>22</sup>

26  
27 The integration of nanowires into large-scale optoelectronic systems and probing the  
28 performance of many single nanowires for large-scale studies remains challenging due to  
29 assembly difficulties.<sup>1</sup> Horizontal single-nanowire devices are usually fabricated using a long,  
30 multi-step and often serial process where each device was especially fabricated on a randomly  
31 located nanowire.<sup>22-24</sup> Devices based on horizontal arrays of nanowires are few, and usually  
32 involve some post-growth assembly method including liquid flow,<sup>25</sup> Langmuir-Blodgett  
33 compression<sup>26</sup> and more recently mechanical shearing onto chemically functionalized patterns.<sup>27</sup>  
34 Although impressive progress has been made, each method has its drawbacks, which often  
35 include length limitations and insufficient control over the alignment and the exact location of  
36 both ends of the nanowires. Another common shortcoming is the difficulty to control the  
37 directionality and orientation of the nanowires, which is important for applications that require a  
38 certain polarity, a directional compositional gradient or axial heterojunctions.

2  
3 The guided growth approach can offer an advantageous alternative to post-growth methods and  
4 facilitate the transition towards large scale single-nanowire research and nanowire-based  
5 functional systems.<sup>28</sup> Guided growth exploits epitaxial and graphoepitaxial relationships between  
6 the nanowire material and the substrate to guide horizontal nanowires during a vapor liquid solid  
7 (VLS) growth, as illustrated in Figure 1A, and bring about well aligned nanowires that grow in  
8 specific and reproducible directions and crystallographic orientations.<sup>29</sup> Furthermore, by  
9 incorporating a top-down nanolithography process, an array of discrete nanowires with control  
10 over their origin, growth direction, crystallographic orientation, and length can be achieved.<sup>30</sup>  
11 More than a decade has passed since the first reports on horizontal epitaxial growth of nanowires  
12 (ZnO on  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>,<sup>31</sup> In<sub>2</sub>O<sub>3</sub> on Si<sup>32</sup> and GaAs on GaAs<sup>33</sup>) and over the last few years a growing  
13 number of materials (GaN,<sup>28</sup> ZnO,<sup>29</sup> Sn-doped In<sub>2</sub>O<sub>3</sub>,<sup>34</sup> InAs,<sup>35</sup> Si,<sup>36</sup> VO<sub>2</sub>,<sup>37</sup> TiO<sub>2</sub>,<sup>38</sup> SnO<sub>2</sub>,<sup>39</sup>  
14 ZnSe,<sup>40</sup> ZnTe,<sup>41</sup> InAsSb,<sup>42</sup> Pb<sub>1-x</sub>Sn<sub>x</sub>Te<sup>43</sup> and CdSe<sup>44</sup>) were successfully used to grow horizontal  
15 nanowires in a similar manner on several substrates ( $\alpha$ -Al<sub>2</sub>O<sub>3</sub>,<sup>28, 40, 41, 44</sup> InAs,<sup>35</sup> Y<sub>2</sub>O<sub>3</sub>-stabilized  
16 ZrO<sub>2</sub>,<sup>34</sup>  $\alpha$ -SiO<sub>2</sub>,<sup>45</sup> SiC,<sup>46</sup> MgAl<sub>2</sub>O<sub>4</sub><sup>47</sup> and GaN<sup>38</sup>). Despite early concerns that their interactions  
17 with the substrate would result in deteriorated crystal quality and optoelectronic properties,  
18 guided nanowires showed excellent optoelectronic properties. Moreover, in the case of ZnSe,<sup>40</sup>  
19 CdSe<sup>44</sup> and CdS (unpublished data) , photodetectors based on guided nanowires outperformed  
20 their vertically-grown counterparts. The latest additions to the horizontal nanowires family,  
21 combined with past reports, accumulate to a relatively wide selection of available optoelectronic  
22 properties including different band gap energies with either electrons or holes as the majority  
23 charge carriers. Despite the growing list of guided nanowires materials and substrates, reports on  
24 guided nanowire heterostructures have been scarce,<sup>48</sup> and core-shell horizontal nanowires have  
25 not yet been reported.

1  
2  
3 Here we report the guided growth of horizontally aligned and epitaxial core-shell nanowires  
4 with controlled orientation on different flat and faceted planes of sapphire. The n-type core is  
5 formed using our recently reported guided ZnSe<sup>40</sup> nanowires and the epitaxial ZnTe p-type shell  
6 is inspired by our report of guided p-type ZnTe<sup>41</sup> nanowires. ZnSe and ZnTe are both interesting  
7 optoelectronic materials with direct band gap energies in the visible range.<sup>49, 50</sup> Furthermore,  
8 theoretical and experimental reports concluded that when the two materials are interfaced, they  
9 form a p-n heterojunction with a type II band alignment, which can be exploited for  
10 photovoltaics and green electroluminescence.<sup>51-54</sup>

11  
12 The guided ZnSe@ZnTe core-shell nanowires grow horizontally and aligned as seen in the  
13 scanning electron microscope (SEM) image in figure 1B. Their orientation is determined by the  
14 interactions between a sapphire substrate and a ZnSe n-type core. In turn, the core acts as an  
15 epitaxial template for the overgrowth of a ZnTe p-type shell forming a p-n radial heterojunction  
16 as shown in figure 1C. The guided growth was carried out in three general modes that dictate  
17 their alignment in reproducible specific directions. The concept and realization of the different  
18 growth modes are presented in figure 1D, including: (a) epitaxial growth along specific lattice  
19 directions on flat, surfaces and graphoepitaxial growth on spontaneously nanofaceted surfaces  
20 along (b) L-shaped nanosteps and (c) V-shaped nanogrooves.

21  
22 The crystallographic orientation, growth directions and epitaxial relations in this three-material  
23 system (sapphire-ZnSe-ZnTe) were characterized and later analyzed in term of strain and strain  
24 relaxation mechanisms using geometric phase analysis (GPA). We find that the crystal phase,  
25 either wurtzite (WZ) or zinc-blende (ZB), and the crystallographic orientations of the ZnSe core  
26 are controlled by its interactions with the flat or faceted sapphire substrates. In almost all cases  
27 the ZnTe shell adapts nicely to the ZnSe-sapphire system, through plastic misfit dislocations or a

more complex strain relief process that combines plastic misfit dislocations with elastic plane-bending. The photoluminescence spectra indicate that a type II heterojunction is formed at the core-shell interface of these surface-bound nanowires. To explore their optoelectronic properties, we exploited the deterministic control over their growth direction and fabricated multiple devices in a parallel and simple manner. The devices based on small arrays of nanowires show dark currents below our 10 fA detection limit, but upon illumination they exhibit a clear rectifying behavior with photovoltaic characteristics.

## 10 11 12 13 RESULTS AND DISCUSSION 14 15

16  
17 We explored the guided growth of ZnSe@ZnTe core-shell nanowires on six different sapphire  
18  
19 ( $\alpha$ -Al<sub>2</sub>O<sub>3</sub>) planes. Four flat surfaces: C (0001), A ( $1\bar{1}20$ ), R ( $\bar{1}120$ ) and M ( $10\bar{1}0$ ) for epitaxial  
20  
21 growth and two faceted surfaces for graphoepitaxial growth: Annealed miscut C (0001) tilted by  
22  
23 2° toward [ $1\bar{1}00$ ] with nanosteps, and annealed M ( $\bar{1}010$ ) with nanogrooves. The VLS growth  
24  
25 was carried out in a quartz tube within a three-zone horizontal tube furnace. The system was first  
26  
27 purged with a 2% H<sub>2</sub> in N<sub>2</sub> gas mixture and held at a constant 500 sccm flow of the gas mixture  
28  
29 while maintaining a 400 mbar pressure for the duration of the process. The gas mixture created a  
30  
31 reducing environment and served as the carrier for the elemental Zn, Se and Te that originated  
32  
33 from high-purity powders of ZnSe and ZnTe. Islands of Au catalyst were patterned beforehand  
34  
35 on the sapphire samples using standard photolithography. Deposition of a thin 1 nm layer of Au  
36  
37 followed by dewetting at 550 °C produced patterned islands of Au catalyst nanoparticles.  
38  
39 Alternatively, commercial Au nanoparticles were used to catalyze the VLS growth. In the first  
40  
41 part of the process, the ZnSe source powder was held at 950-1000°C in the first heating zone of  
42  
43 the furnace, while the samples were placed downstream in the second heating zone and held at  
44  
45 720-770°C. After a 15 min growth period, the ZnSe source was replaced with ZnTe *in-situ* using  
46  
47 a homemade, magnetically controlled exchange system. Once the ZnTe powder was in place, a  
48  
49 second growth period commenced with the powder held at 730°C and the samples at 680°C for 5  
50  
51 min (see Methods and Supporting Information for further details).  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Nanowires and nanobelts grow vertically in the center of the Au catalyst pattern while  
4 horizontally aligned nanowires grow from the pattern edges where the clean sapphire surface is  
5 accessible. The vertical nanostructures can be easily removed by a mild sonication in isopropyl  
6 alcohol for a few seconds. When sparsely dispersed Au nanoparticles (10–50 nm) are used as  
7 catalyst to gain better control over the catalyst nanoparticle size, the clean sapphire surface is  
8 accessible to many more nucleation sites, and under these conditions the horizontal growth is  
9 dominant over the vertical growth. The typical total thickness of the horizontal core-shell  
10 nanowires varies between 50 and 200 nm. While our growth parameters were adjusted so that the  
11 thicknesses of the core and shell are roughly the same, these thicknesses can be adjusted by  
12 varying the catalyst size and the duration of each growth period. The length of the guided  
13 nanowires can vary from few microns in a short process, and up to 100  $\mu\text{m}$  in a 20 min process.  
14 They are slightly tapered and the shell overgrowth is not entirely uniform.

15  
16 Since the nanowires are bound to the surface, in order to explore their elemental composition,  
17 crystallographic structure, epitaxial relations and strain relief mechanisms under a high-  
18 resolution transmission electron microscope (HRTEM) and an aberration-corrected scanning  
19 TEM (STEM), thin (50-100 nm) slices were cut across and along the nanowires using a focused  
20 ion beam (FIB).

### 21 22 **Epitaxial guided growth on flat sapphire substrates**

23  
24 On C (0001) sapphire the guided core-shell nanowires grow along the six isoperiodic M  
25  $\pm\langle 10\bar{1}0 \rangle$  directions, reflecting the threefold symmetry and three glide planes of the substrate  
26 (figure 2A). This behavior resembles previous guided growth reports of GaN,<sup>28</sup> ZnO,<sup>29</sup> ZnSe,<sup>40</sup>  
27 ZnTe<sup>41</sup> and CdSe<sup>44</sup> nanowires on C-plan sapphire. HRTEM imaging of a cross sectional lamellae

1  
2  
3 unveil a distinct core-shell structure where both the core and shell are bound to the sapphire  
4 substrate. The selected area fast Fourier transform (FFT) of this sapphire-ZnSe-ZnTe architecture  
5 reveals clear epitaxial relations between the three materials. Both ZnSe core and ZnTe shell have  
6 a ZB crystal structure and their growth axis is along the  $[11\bar{2}]$  direction. The planes parallel to  
7 the substrate are (111), which are perfectly aligned with the (0006) planes of the sapphire, while  
8 their transverse  $(1\bar{1}0)$  planes are aligned with the orthogonal  $(11\bar{2}0)$  planes of sapphire.  
9

10 Surprisingly, when examining the guided nanowires on A  $(11\bar{2}0)$  sapphire we found a six-  
11 directional growth (figure 2B) that resembles the growth we observed on C (0001) (figure 2A).  
12 On A  $(11\bar{2}0)$  the guided core-shell nanowires grow along two M  $\pm[1\bar{1}00]$  directions and 4 S  
13 directions  $\pm[1\bar{1}01]$  and  $\pm[1\bar{1}0\bar{1}]$ . The M and S directions are separated by a  $61.5^\circ$  angle while  
14 adjacent S directions are separated by a  $57^\circ$  angle. Selected area fast Fourier transform (FFT) of  
15 nanowires that grow on A-plane sapphire along the M  $\pm[1\bar{1}00]$  directions reveal that they have  
16 the same crystallographic behavior as the guided nanowires on C-plane. Both the ZnSe core and  
17 ZnTe shell have a ZB crystal structure and their growth axis is along the  $[11\bar{2}]$  direction. The  
18 epitaxial relations are still clearly observed in the selected area FFT. In this case, the planes that  
19 are parallel to the substrate are still (111) despite the fact that the relevant sapphire planes are  
20 the  $(11\bar{2}0)$  planes and not the (0006) as in the previous case. Accordingly, the transverse planes  
21 of the core and the shell are the  $(1\bar{1}0)$  planes, which are aligned with the orthogonal (0006)  
22 planes of sapphire.  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48

49 The fact that both on A-plane and on C-plane the nanowires exhibit a six-directional growth  
50 with the same crystallographic orientation is peculiar since we generally expect different  
51 sapphire planes to induce different growth directions and/or crystallographic orientations for  
52 guided nanowires. The growing horizontal nanowires should be inclined to minimize the  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 interfacial energy and strain that is accumulated during the heteroepitaxial growth. Therefore, in  
4  
5 order to better match the different symmetries and atomic structures of the substrates, the  
6  
7 preferred growth directions and crystallographic orientation of the growing nanowires is  
8  
9 expected to change. In order to shed light on the observed results, it is sufficient to examine more  
10  
11 carefully the relations between the sapphire substrate and the ZnSe core since they determine the  
12  
13 growth direction and crystallographic orientation of the core and consequently also of the shell.  
14  
15 More specifically, we focus on the transverse direction, which was suggested as dominant at  
16  
17 determining the crystallographic orientation for guided nanowires in high-mismatch systems.<sup>38</sup>  
18  
19

20  
21  
22 For guided nanowires on both A and C-plane sapphire, the mismatch at the transverse  
23  
24 direction, was relatively high and varied considerably for different sapphire planes and growth  
25  
26 orientations (Table S1). A top view of the atomic configuration, of only the topmost unit cell of  
27  
28 sapphire and the lowest ZnSe unit cell, implies that a six-directional growth is reasonable on both  
29  
30 planes. Taking into consideration these two findings, and assuming a thermodynamically  
31  
32 governed growth, it seems that in these conditions the energetic gain of exposing specific facets  
33  
34 during the growth is larger than the energy cost of atomic-matching differences. This energetic  
35  
36 balance results in the repeating  $[11\bar{2}]$  crystallographic orientation, as in this scenario, the fact  
37  
38 that the A-plane has an overall structure that encourages a six-directional growth is more  
39  
40 important than the atomic structure along those directions.  
41  
42  
43  
44  
45

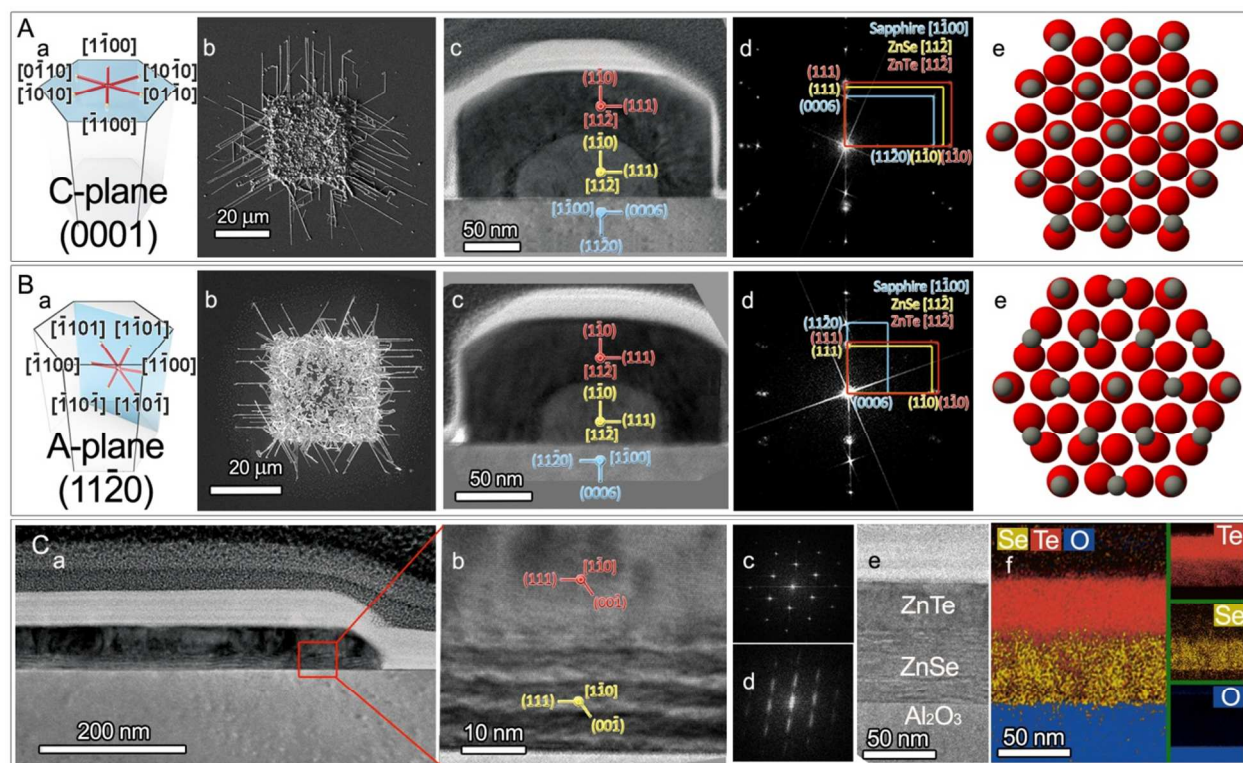

46  
47 It is worth mentioning that the behavior of the ZnSe-sapphire system reported herein is  
48  
49 different than that reported in our previous work.<sup>40</sup> Many reports in the literature, including our  
50  
51 own, demonstrate changes in epitaxial growth of nanowires due to changes in the growth  
52  
53 parameters.<sup>55</sup> We believe that our recently assembled growth system, and resulting changes in  
54  
55 the growth conditions, are responsible for the different result in this work compared to our  
56  
57  
58  
59  
60

1  
2  
3 previous study. We find that different guided growth regimes can be observed, in a reproducible  
4 matter, within the same ZnSe-sapphire system as a result of different growth parameters. This  
5 might suggest that depending on the growth conditions, at least with some material systems,  
6 there is not one, but several guided growth behaviors that could be individually addressed.  
7 Perhaps different conditions tilt the energetic balance towards specific growth behaviors in a  
8 thermodynamically governed process. Otherwise, the different behaviors can be kinetically  
9 controlled, as it is known that certain facets form faster than others even when they are not  
10 thermodynamically more stable.<sup>56</sup> In any case, this suggests that a high-resolution control over  
11 the growth conditions can bring about adjustable guided growth, where one can choose the best  
12 suited direction and crystallographic orientations for a specific application.

25  
26

27 The ZB  $[11\bar{2}]$  and the WZ  $[10\bar{1}0]$  crystallographic growth directions are almost identical when  
28 observed through only a selected area FFT of the cross section. In order to differentiate between  
29 the two, and determine unambiguously the growth axis of the guided nanowires, lamellae along  
30 the growth direction of guided nanowires on both sapphire planes were prepared. The HRTEM  
31 images and analysis for a guided nanowire on A-plane is presented in figure 2C along with  
32 energy filtered TEM (EFTEM) that discloses the expected locations of the different elements in  
33 the nanowire. The selected-area FFT confirmed the ZB  $[11\bar{2}]$  growth direction since the  
34 orthogonal direction was clearly the ZB  $[1\bar{1}0]$  direction for the ZnTe shell. Since the lamella was  
35 thicker than the core, a moiré pattern was formed where the ZnSe and ZnTe lattices overlap. It  
36 was still possible to determine the ZB  $[1\bar{1}0]$  of the core from the FFT and the moiré periodicity.  
37 The lamella along a nanowire on C-plane can be found in figure S2A along with moiré  
38 periodicity calculations.

1  
2  
3 Further atomic-resolution aberration-corrected HAADF STEM analyses obtained on the  
4 lamellae cut along the guided nanowires growth direction on A-plane confirmed the ZB structure  
5  
6  
7  
8 for both the core and the shell (Figure S3). In addition, the crystal polarity of the nanowire could  
9  
10 be extracted from the HAADF-STEM images<sup>57</sup> confirming that the NW is B-polar (Se/Te or  
11  
12 anion polar) along the guided growth direction and A-polar (Zn or cation polar) in the vertical  
13  
14 direction from the substrate. The B-polarity along the guided growth direction is in good  
15  
16 agreement with the usual polarity observed in vertically grown ZnTe NWs.<sup>57, 58</sup>  
17  
18  
19

20 Once the crystallographic orientation and polarity of the core and shell are known, we can also  
21  
22 gain insight into the morphology of the shell and its mechanism of formation. During our efforts  
23  
24 to find the growth parameters for the desired morphology and thickness of the shell overgrowth,  
25  
26 we observed some extreme cases ranging from a massively thick shell to an incomplete shell  
27  
28 growth (figure S4a). Even at our optimized condition for shell overgrowth on C and A-plane  
29  
30 sapphire, it is clear that the shell overgrowth is not entirely uniform (figure S4b). The results  
31  
32 containing an incomplete shell and HRTEM images from the lamellae cut along the axis of the  
33  
34 nanowire with a continuous shell (figure 4Sc-d) imply that our shell formation resembles the  
35  
36 previously reported Plateau–Rayleigh crystal growth.<sup>59</sup> The epitaxial shell nucleates in several  
37  
38 nucleation centers along the nanowire and, given the right parameter, the centers grow along the  
39  
40 nanowire and merge to form a continuous shell. This mechanism is further discussed in the  
41  
42 Supporting Information.

1  
2  
3 The guided growth of our core-shell nanowires on R ( $1\bar{1}02$ ) sapphire is predominantly along  
4 two non-isoperiodic directions of the sapphire substrate,  $[\bar{1}101]$  and  $[\bar{1}3\bar{2}2]$  as depicted in figure  
5 S5. Lamellae were cut for both growth directions. Despite growing along non-isoperiodic  
6 directions, all nanowires presented the same WZ crystal structure with the same  $[\bar{4}223]$  growth  
7 direction both for the ZnSe core and ZnTe shell. The nanowires had a trapezoid form with  
8 distinct  $(01\bar{1}0)$  and  $(1\bar{1}02)$  facets and it is quite noticeable that the ZnTe shell is not isotropic  
9 and grows preferably over the  $(1\bar{1}02)$  planes of the ZnSe core. Further manipulating the growth  
10 conditions can lead to a completely facet selective growth. On flat M ( $10\bar{1}0$ ) sapphire we  
11 observed more unusual growth directions. The guided core-shell nanowires grow along  $\pm[1\bar{2}10]$ ,  
12  $\pm[\bar{1}2\bar{1}\bar{3}]$ , and  $\pm[\bar{1}2\bar{1}6]$  directions of the sapphire substrate (figure S5). The analyzed nanowires  
13 have a WZ crystal structure and grow along the polar  $[0001]$  direction. The unusual phenomena  
14 observed with R-plane and M-plane, including the anisotropic shell growth and the growth along  
15 multiple relatively rare and different crystallographic orientations, are further discussed in the  
16 Supporting Information.

### 36 **Graphoepitaxial guided growth on faceted sapphire substrates**

37  
38  
39 One of the strengths of the guided growth approach is the ability to control the growth  
40 direction of the horizontal nanowires through surface manipulation. Past studies have shown that  
41 nanowires can grow along nanosteps and nanogrooves on nanofaceted sapphire substrate.<sup>23, 24, 40-</sup>  
42  
43  
44  
45  
46  
47 <sup>42</sup> This mode of guided growth, which we refer to as graphoepitaxy, has proven to be dominant  
48 over epitaxial growth, and essentially overrules the epitaxial relations between the sapphire and  
49 the nanowire.<sup>28, 29, 40, 41, 44</sup> This was the case also for the core-shell guided nanowires, as can be  
50 seen in figure 3. The six-directional growth of guided nanowires on flat C-plane is overruled by  
51 annealing a C (0001) sapphire substrate that was miscut 2 degrees towards  $[1\bar{1}00]$  to form an  
52  
53  
54  
55  
56  
57  
58  
59  
60

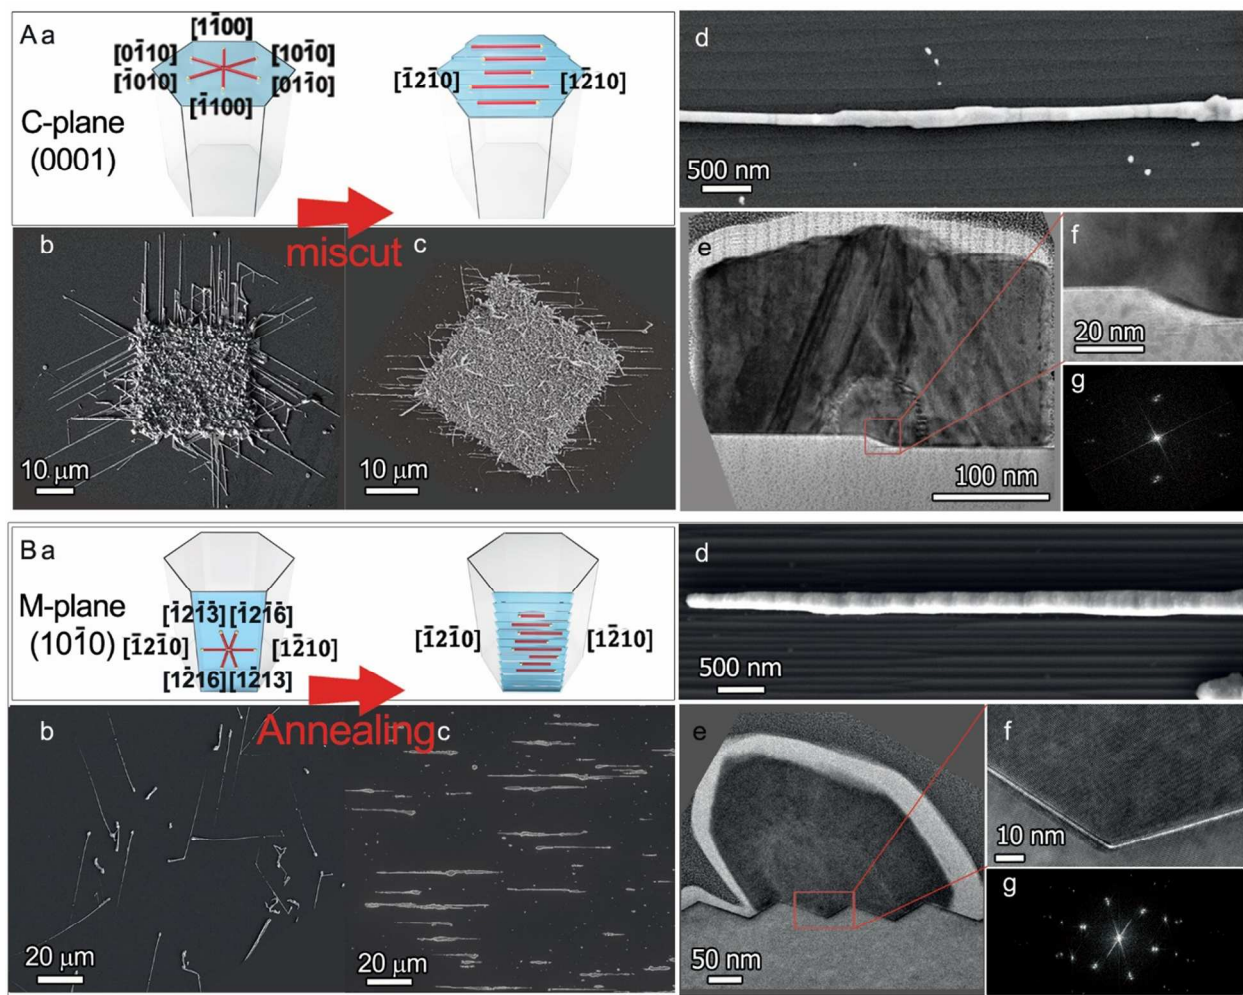

1  
2  
3 array of L-shaped nanosteps due to step-bunching of the high-index.<sup>60</sup> The nanowires in this case  
4  
5 are guided by these nonosteps and grow along them to the  $\pm[1\bar{2}10]$  directions of the sapphire  
6  
7 substrate (figure 3A). Despite nice alignment along specific sapphire directions, these nanowires  
8  
9 are more ragged than the nanowires grown on flat substrates. Furthermore, unlike the very  
10  
11 homogeneous crystallographic structure observed on flat substrates, the nanowires that grow  
12  
13 along the nanosteps have a variety of crystallographic orientation and crystal phases (figure S6  
14  
15 and table S2).  
16  
17  
18  
19

20 Flat M (1010) sapphire is thermodynamically unstable. Annealing at elevated temperatures  
21  
22 (*e.g.* 1600°C) causes surface restructuring and the more stable S-plane and R-plane facets create  
23  
24 well-structured periodic nanogrooves.<sup>60</sup> The horizontal core-shell nanowires grow along the two  
25  
26  $\pm[1\bar{2}10]$  directions of the nanogrooves instead of the six directions of flat M (10 $\bar{1}$ 0) sapphire  
27  
28 (figure 3B). Similar to the findings on a miscut C-plane, the guided core shell nanowires that  
29  
30 grow in the graphoepitaxial growth mode were more ragged, and presented a few different cross-  
31  
32 sectional structures with some variation of crystallographic orientations and crystal phases.  
33  
34  
35

36 In a previous work,<sup>40</sup> we mentioned that graphoepitaxial nanowires need to adapt  
37  
38 simultaneously to two sapphire planes and their energetic constraints. We hypothesized that the  
39  
40 accumulated strain is manifested in a rougher surface and lesser uniformity in growth axes. In the  
41  
42 present case, since the shell growth is a vapor-solid (VS) growth, it is highly influenced by the  
43  
44 initial smoothness of the guided core. Small imperfections and roughness in the core can be  
45  
46 highlighted when the shell forms and the end result is often bulky. With that said, some of the  
47  
48 guided nanowires have high aspect ratio and faceted rectangular cores exposing smooth lateral  
49  
50 facets, which proved ideal as templates for the shell growth (figure S6 and table S2).

1  
2  
3 The guided growth of horizontal core-shell ZnSe@ZnTe nanowires on all these different  
4 substrates extends the generality of the approach to nanowire heterostructures while providing  
5 further empirical data toward its understanding. Although the exact mechanism of guided growth  
6 is not yet fully elucidated, a few models have rationalized the horizontal growth of nanowires,  
7 either by considering a fully faceted limit of a continuum model taking into consideration facet  
8 dynamics, droplet statics, and the energy required to introduce a new facet,<sup>61</sup> or by introducing  
9 thermal fluctuations to a thermodynamic description.<sup>62</sup> Hopefully the growing empirical database  
10 along with other, more recent, reports including those exploring the Gibbs-Thomson effect in  
11 horizontal nanowires<sup>63</sup> and the VLS etching of surfaces by running gold nanodroplets<sup>64</sup> will  
12 accumulate to a comprehensive understanding of this phenomenon.

### Stress relief mechanisms in guided core-shell nanowires

During the shell formation, a complex stress relief mechanism is taking place in order to minimize the elastic energy on the two mismatched material systems. From Fourier analysis on the atomic-resolution aberration-corrected HAADF-STEM micrograph in Figure 4(a) we can notice a triple spot instead of the double core-shell spot expected. One spot corresponding to the ZnSe planes of the core, and a double spot arising from the shell. This double spot corresponds to equal plane spacings, but, as a result of plane bending, there is a  $4^\circ$  angle between the planes on the left part and the right part of the shell.

Through geometrical phase analysis, the dilatation and rotation maps of ZnSe@ZnTe (111) planes have been obtained. By keeping the core as a reference, we can measure a mean dilatation of 8.8 % in shell plane spacing, which is higher than the expected 7.4 % (for a perfectly relaxed ZnSe@ZnTe), indicating tensile strain on the shell structure. More information can be obtained from the rotation map, where we observe both plastic and elastic strain relaxation mechanisms.<sup>65</sup>

<sup>66</sup> A set of misfit dislocations in the vertical planes are visible (white arrows in Figure 4e), showing a plastic strain relaxation while at the same time we observe a general rotation on planes at both sides of the shell with a mean value of  $+2^\circ$  (right side shell planes) and  $-2^\circ$  (left side shell planes) which are consistent with the rotations measured in the FFT. This plane bending phenomena seem to dramatically depend on the core morphology, observing lower angles when the core surfaces are flatter. Further study on the relaxation mechanisms on the different structures depending on core morphology and substrate orientation will be performed in the future.

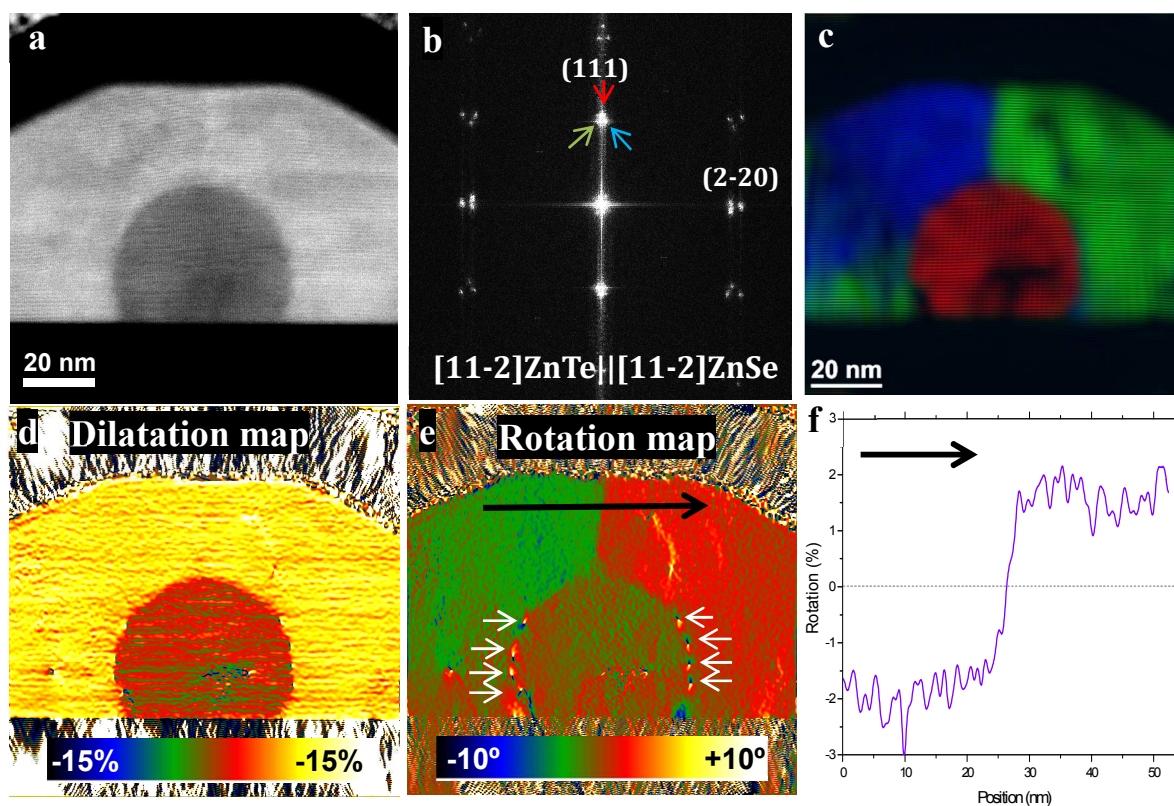

Figure 4. (a) Cross-sectional atomic resolution HAADF-STEM micrograph of a guided ZnSe@ZnTe core-shell nanowire along sapphire A-plane and (b) its corresponding FFT. (c) Structural map obtained by filtering the spots of the FFT. (d) Dilatation and (e) rotation maps obtained through Geometrical Phase Analysis (GPA) along the ZnSe and ZnTe (111) planes. (f) Rotation profile obtained along the arrow indicated in (e). White arrows in (e) point to the misfit dislocations.

### Optical properties of the guided ZnSe@ZnTe core-shell nanowires

Room-temperature photoluminescence (PL) spectra were obtained with a micro-Raman system (Horiba LabRAM HR Evolution) using a 325 nm He-Cd laser. In order to compare the optical behavior of the core-shell system with its individual components, we measured the PL spectra of single ZnSe and ZnTe guided nanowires that were grown separately in the above mentioned

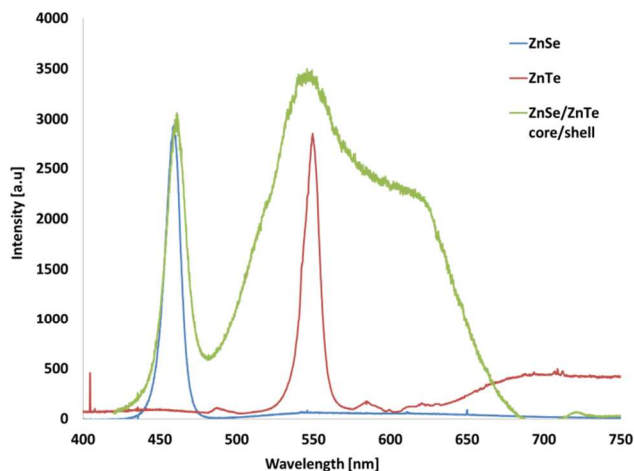

1  
2  
3 growth conditions. PL measurements of the ZnSe@ZnTe core-shell guided nanowires were  
4 conducted as well (figure 5). The typical PL spectrum of a single ZnSe guided nanowire on C  
5 (0001) sapphire had only one narrow peak at 459 nm ( $\sim 2.7$  eV) that corresponds to the near-  
6 band-edge (NBE) emission. For ZnSe, another broad deep-level (DL) emission peak centered at  
7 635 nm (1.95 eV) is often observed and attributed to intrinsic point defects (IPDs),<sup>67</sup> the lack of  
8 this defect band in our measurements indicates a high crystal quality of the ZnSe core. The case  
9 of a typical ZnTe guided nanowire on C (0001) sapphire was similar, with one narrow peak at  
10 549 nm ( $\sim 2.26$  eV) that corresponds to its NBE emission. Notably, a common broad DL  
11 emission peak centered at 670 nm (1.85 eV) due to IPDs is not observed.<sup>41</sup>

60

The typical PL spectrum of a single ZnSe/ ZnTe core-shell guided nanowire on C (0001) sapphire has a sharp peak at 461 nm which corresponds to the ZnSe NBE emission with a 2 nm red shift. The second broad peak, with a dominant peak and a strong shoulder, was fitted to 3 Gaussians, one with a distinctive peak at 546 nm, and two that comprise the shoulder. We attribute the peak at 546 nm to the NBE emission of the ZnTe shell. Notably, this peak is broader and about 3 nm blue-shifted compared to the emission of the guided ZnTe nanowires. We suspect that the small shifts in the NBE emission of ZnSe and ZnTe might originate from the strain induced by the formation of the core-shell structure. Furthermore, the broadening of the NBE emission is possibly due to strain inhomogeneity along or across the growth axis of the nanowires. Within the shoulder, there is one low-intensity Gaussian at 597 nm and a higher intensity one at 612 nm (see figure S7).<sup>68</sup> As for the orange emission at 597 nm and 612 nm, we have to consider two possible causes, either a DL emission that originates from the formation of IPDs during the shell growth or a type II recombination emission.

60

When considering the formation of IPDs as a possible origin of the orange emission at 597 nm and 612 nm, one should take into account the commonly formed DL emissions for the corresponding materials. For ZnSe, the common DL emission is around 635 nm and for ZnTe around 670 nm. For both materials the common DL emission wavelengths are longer than those observed in the spectrum (612 nm). Thus even if we assume that IPDs are formed during the shell growth, it is still unlikely that they are responsible for the orange emission that is observed in the guided ZnSe@ZnTe core-shell nanowires. A different possible origin of the orange emission is a type II recombination at the ZnSe-ZnTe heterojunction between electrons from the conduction band of the ZnSe core and holes from the valence band of the ZnTe shell (figure 1C). Theoretical calculations and experimental data show that the n-type ZnSe and p-type ZnTe form a type II p-n heterojunction. The energy gap between the ZnSe conduction band and the ZnTe valence band is estimated at  $\sim 2.0$  eV<sup>52-54, 69</sup> (620 nm), which is close to the 612 nm emission peak that we observe in the orange emission shoulder. The slight shift can be attributed to strain as a result of epitaxial mismatch that could modulate the band structure.<sup>70</sup> In principle, time-resolved PL at low temperatures could establish the origin of the orange emission.<sup>68</sup> However, these measurements were not possible with our current setup, and are hence beyond the scope of this report. In any case, considering the electronic nature of these materials and the fact that common DL emission band of ZnSe and ZnTe do not match the observed orange emission, this is most likely a type II recombination.

**Figure 5.** Room temperature PL spectra of single ZnSe (blue), ZnTe (red) and ZnSe@ZnTe core-shell guided nanowires (green) on a sapphire substrate. The peak at 460 nm corresponds to the NBE emission of ZnSe, the peak at 549 nm corresponds to the NBE of ZnTe. The orange emission around 600 nm that causes the shoulder in the core-shell spectrum is attributed to type II recombination.

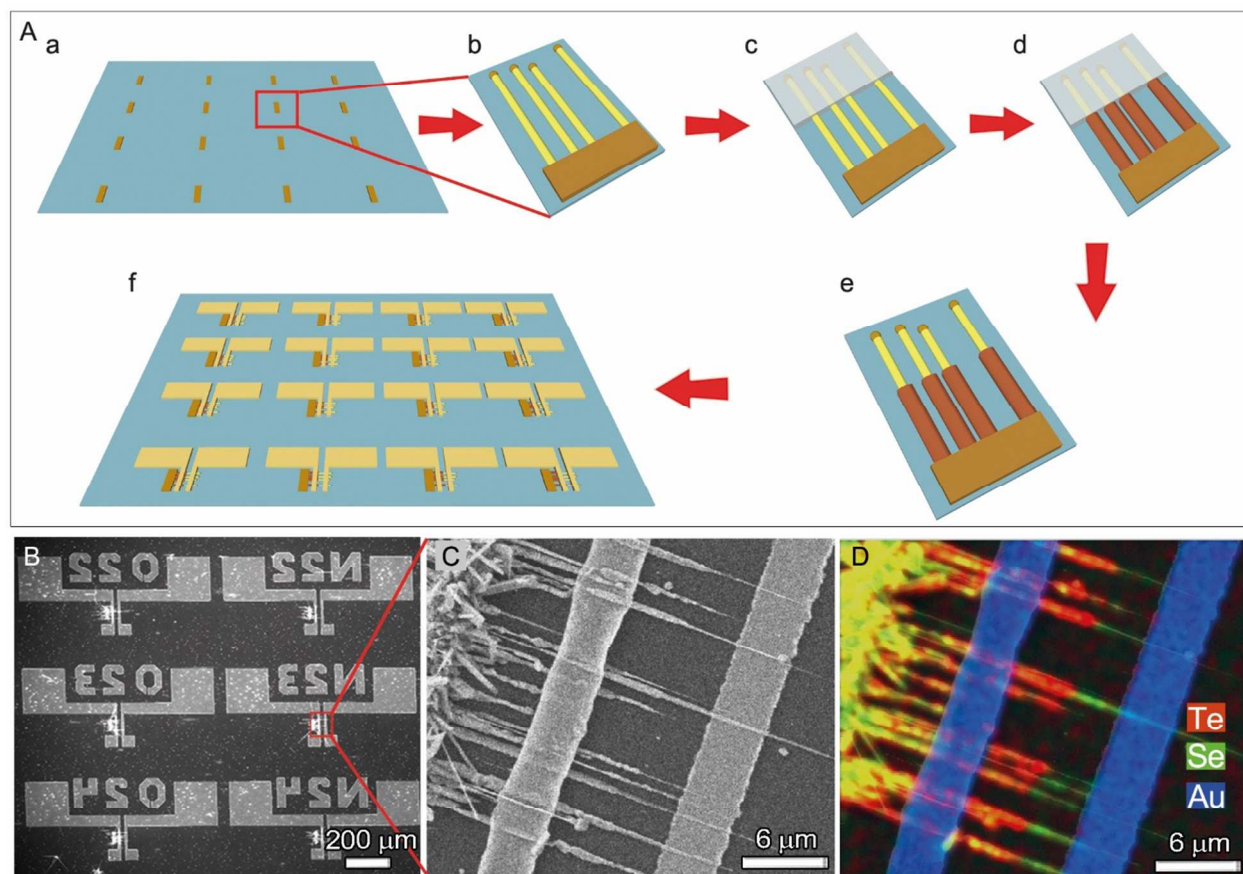

### Optoelectronic properties of the guided ZnSe@ZnTe core-shell nanowires

Previous studies conducted on guided nanowires concluded that despite early concerns, the substrate-nanowire interactions do not cause deterioration in the crystal quality and the optoelectronic properties of the nanowires.<sup>40, 41, 44</sup> On the contrary, guided nanowires usually show excellent optoelectronic properties. In the case of ZnSe,<sup>40</sup> CdSe<sup>44</sup> and CdS (unpublished data), photodetectors based on guided nanowires outperformed their vertical counterparts. This work demonstrates core-shell nanowires that are guided through surface-nanowire interactions. In this configuration, the ZnSe core and ZnTe shell are expected to form a radial p-n heterojunction, therefore, probing the optoelectronic behavior of this system is essential for its understanding.

1  
2  
3 In order to probe the optoelectronic properties of the core-shell guided nanowires we exploited  
4 the deterministic control over their location and growth direction and fabricated multiple devices  
5 using only parallel fabrication steps. The growth of the guided core-shell nanowires, as described  
6 earlier, resulted with a completely covered core. However, in order to probe the radial  
7 heterojunction, one electrode should be in contact with the p-type shell while the other one  
8 should be connected to the n-type core. ZnSe and ZnTe are very similar chemically hence  
9 selective etching to expose part of the core was not perused. Instead, we formulated a fabrication  
10 process where certain segments of the core are masked prior to the shell growth in order to have  
11 them accessible to direct contact with an outer electrode, as illustrated in figure 6. In this scheme,  
12 after the growth of a guided ZnSe core as described earlier, standard photolithography and  
13 electron-beam evaporation of a 200 nm SiO<sub>2</sub> protective layer was carried out on part of the core.  
14 Next the shell was grown, followed by wet etching of the protective layer. The final step was  
15 patterning and depositing Ti/Au electrodes (10 nm/90 nm), again with photolithography and  
16 electron-beam deposition so that one electrode contacted the bare ZnSe core while the other one  
17 contacted the shell (see methods for further details). In this manner, multiple devices were  
18 fabricated using only parallel fabrication steps. Alternatively, the photolithography steps can be  
19 replaced with e-beam lithography steps for better control over the dimensions and location of the  
20 contacts. The number of nanowires in each device is determined by the yield of the ZnSe core  
21 growth and the catalyst size. The yield can vary with the growth parameters while the catalyst  
22 size is determined by the photolithography process. As shown in figure 6B-D, a device that was  
23 fabricated in this manner has between 1 and 15 core-shell guided nanowires that cross a 2-8 um  
24 gap between the electrodes. A typical cross-section of the nanowires is 50 nm and 150 nm for the

core and core-shell structure respectively. Energy-dispersive X-ray spectroscopy (EDS) mapping validates that within the gap the ZnSe core is partly covered with the ZnTe shell.

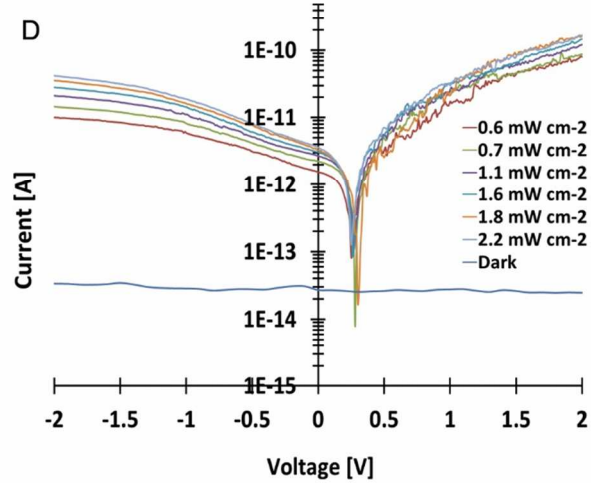

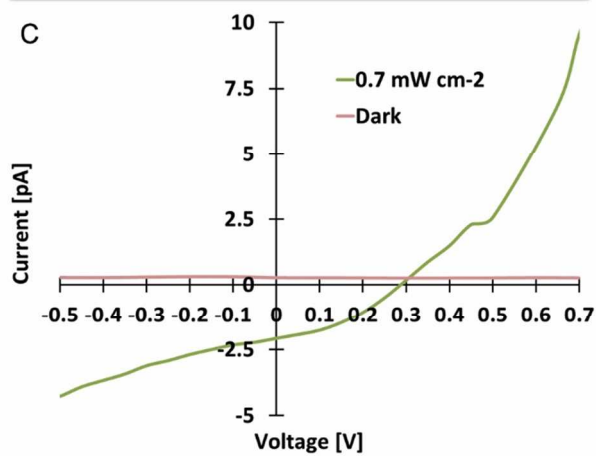

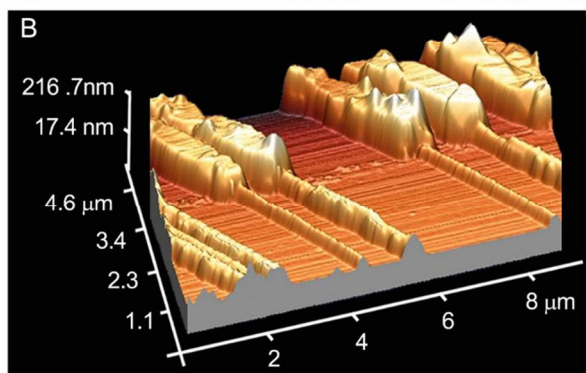

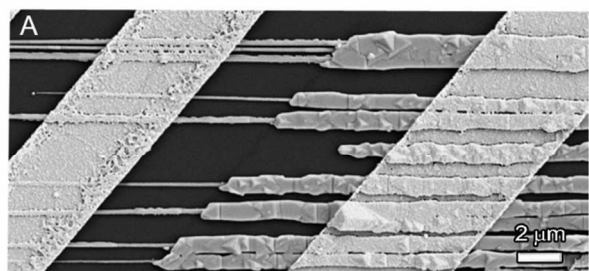

**Figure 6.** Parallel fabrication of multiple devices based on ZnSe@ZnTe Core-shell guided nanowires (A) Schematic illustration of the fabrication steps: (a) catalyst islands deposition followed by (b) ZnSe guided core growth, (c) protective shell deposition and (d) ZnTe shell growth before (e) etching of the protective layer and (f) deposition of electrodes. (B) SEM image of a typical array of devices. (C) Magnification of a single device and its (C) SEM-EDS elemental mapping.

Once the devices were fabricated, we probed the optoelectronic properties of the guide core-shell nanowires using a Janis ST-500 probe system with a Keithley 4200-SCS. *I-V* measurements were done under vacuum, at room temperature, in dark condition ( $16 \mu\text{W}/\text{cm}^2$  ambient light) and

1  
2  
3 under a 405 nm laser illumination at different intensities. In figure 7 a typical device with 9  
4 parallel core-shell nanowires can be seen along with its 3D height map and current-voltage ( $I$ - $V$ )  
5 curves. The devices exhibit very low dark currents as our 10 fA detection limit was not sufficient  
6 to measure a current in dark conditions. This is not surprising considering our previous report on  
7 dark currents below our 10 fA detection limit in photodetectors based on ZnSe guided  
8 nanowires.<sup>40</sup> However, under illumination of 0.7 mW/cm<sup>2</sup>  $I$ - $V$  curves could be measured due to  
9 the generated photocurrent, and a rectifying behavior was observed as expected for a p-n  
10 heterojunction diode. Furthermore, an open-circuit voltage of  $\sim 0.3$ V was measured and a short-  
11 circuit current of  $\sim 2$  pA. Due to the extremely low dark current, only the lower limit of the on/off  
12 ratio and responsivity can be determined when assuming the dark current is at the 10 fA noise  
13 level. The responsivity is defined as  $R_\lambda = \Delta I / PS$ , where,  $\Delta I$  is the difference between the  
14 photocurrent ( $I_{\text{photo}}$ ) and dark current ( $I_{\text{dark}}$ ),  $P$  is the laser power density, and  $S$  is the effective  
15 illumination area estimated by the electrode gap, nanowires diameter and number of nanowires.  
16 The lower bound responsivity of this device is estimated at 0.2 A/W at zero bias. When the  $I$ - $V$   
17 measurements were conducted under increasing illumination intensities (figure 7D), the  
18 magnitude of the short-circuit current increased linearly while the open-circuit voltage remained  
19 approximately constant. In principle, this core-shell p-n heterojunction should exhibit  
20 electroluminescence, which would provide further information about its band alignment and  
21 deep level states. However, using our commercial micro-Raman/PL system, we did not detect  
22 any measureable electroluminescence. One possible reason for the low intensity of  
23 electroluminescence is the very low dark conductance of the ZnSe nanowires.

1  
2  
3 The performance of a device or an array of devices can be adjusted in relative ease by  
4 changing the number of nanowires in each device. This can be achieved by changing the size of  
5 the catalyst pattern and creating larger devices, or by varying the growth parameters to receive  
6 different yields. The ability to fabricate simultaneously a large number of devices based on one,  
7 several or many core-shell nanowires with a radial heterojunction in the same crystallographic  
8 orientation can be used as a powerful tool for both research and applications.<sup>71</sup>

### 13 CONCLUSIONS:

14  
15  
16 In summary, we have demonstrated the guided growth of horizontal core-shell nanowires,  
17 specifically ZnSe@ZnTe with controlled orientation on six different flat and faceted planes of  
18 sapphire (Table S3, Supporting Information). Both epitaxial growth along specific lattice  
19 directions on flat surfaces and graphoepitaxial growth along nanosteps and nanogrooves were  
20 realized. We analyzed the crystallographic orientations and stress relief mechanisms of the  
21 guided core-shell nanowires. The crystal phase, either wurtzite or zinc-blende, and  
22 crystallographic orientations of the core and shell are controlled by the substrate that is selected  
23 and the growth conditions. The ZnSe-sapphire epitaxial and graphoepitaxial relations and the  
24 resulting core crystallographic orientation determine the shell behavior which adapts to the  
25 atomic structure of the core through a combination of plastic misfit dislocations and elastic  
26 plane-bending strain-relief processes.

40  
41

42 We exploited our deterministic control over both the growth direction and the crystallographic  
43 orientation of the guided nanowires to fabricate multiple devices using only parallel steps. The  
44 devices based on small arrays of nanowires with a radial p-n heterojunction show dark currents  
45 below our detection limit of 10 fA. Upon illumination, the devices exhibit a rectifying behavior  
46 with photovoltaic characteristics and currents up to 5 nA (under a 405 nm,  $2.5\text{ mW}/\text{cm}^2$   
47 illumination and 2 V forward bias). The simultaneous fabrication of a large number of devices

1  
2  
3 based on one, several or many nanowires in the same crystallographic orientation can be utilized  
4  
5 for statistical research or applications that require easy fabrication and scalability.  
6  
7

8 The B-polar (Se/Te polar) atomic configuration along the growth direction, implies that  
9  
10 nanowires that grow along a certain sapphire direction will have the same polarity. Therefore the  
11  
12 guided growth can yield homogenous arrays of nanowires with the same polarity, which would  
13  
14 be highly beneficial for polar sensitive applications. The introduction of guided nanowire  
15  
16 heterostructures could enable the production of many complex semiconductor structures with  
17  
18 controlled electronic and optoelectronic properties not available by other means.  
19  
20  
21  
22  
23

#### 24 METHODS:

25  
26  
27  
28 **ZnSe@ZnTe core-shell guided nanowires synthesis.** The substrate preparation and catalyst  
29  
30 deposition and patterning are describe previously<sup>29</sup> and illustrated in the figure S1 in the  
31  
32 Supporting Information. The VLS growth was carried out in a three-zone horizontal-tube  
33  
34 furnace. The quartz tube reactor was purged with a N<sub>2</sub> (99.999%, Gordon Gas) and H<sub>2</sub>  
35  
36 (99.99995%, Parker Dominic Hunter H<sub>2</sub>-generator) 49:1 mixture and kept 400 mbar with a  
37  
38 constant 500 sccm flow of the N<sub>2</sub>/H<sub>2</sub> mixture. In the first part of the process, the ZnSe source  
39  
40 powder (99.99% SPI Supplies) was held at 950-1000°C in the first heating zone of the furnace,  
41  
42 while the samples were placed downstream in the second heating zone and held at 720-770°C.  
43  
44 After a 15 min growth period, the furnace was moved so that the source and the sample are not  
45  
46 heated. The furnace temperatures were set to 730°C at the first zone and 680°C at the second  
47  
48 heating zones and using a home built magnetic crucible holder the ZnSe powder was pulled  
49  
50 away and replaced with a ZnTe powder (99.99% Sigma-aldrich). Once the furnace reached the  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 desired temperatures, it was moved over the sample and ZnTe powder to enable the 5 min shell  
4  
5 growth.  
6  
7

8  
9 **Structural characterization.** The nanowires were imaged with a scanning electron  
10  
11 microscope (Supra 55VP FEG LEO Zeiss). In order to analyze the crystallographic structure and  
12  
13 orientations of the nanowires and substrate, a focused-ion beam (FIB, FEI Helios 600 Dual Beam  
14  
15 microscope) was used to cut thin (50-100 nm) lamellae across or along the nanowire, which were  
16  
17 later inspected under a high-resolution transmission electron microscope (HRTEM, FEI Tecnai  
18  
19 F30). The HRTEM images were analyzed using fast Fourier transform (FFT) from selected areas  
20  
21 across the nanowire, and the FFT peaks were fitted to the crystallographic tables of bulk ZnSe,  
22  
23 ZnTe and sapphire. The core-shell nanostructures were also studied by atomic resolution high  
24  
25 angle angular dark-field scanning transmission electron microscopy (HAADF-STEM) using a  
26  
27 probe corrected FEI Titan 60–300 equipped with a high brightness field emission gun (XFEG)  
28  
29 and a CETCOR corrector from CEOS. The obtained data allowed us to perform geometric phase  
30  
31 analyses (GPA) for strain measurements.<sup>72</sup>  
32  
33  
34  
35  
36  
37

38  
39 **Optical characterization.** Photoluminescence (PL) measurements were done using a micro-  
40  
41 Raman/micro-PL system (Horiba LabRAM HR Evolution). A 325 nm He-Cd laser was focused  
42  
43 on the nanowire through a reflective 70X objective lens. The PL signal was collected using the  
44  
45 same objective and sent to a 300 lines/mm grating and an EMCCD camera.  
46  
47

48  
49 **Device fabrication and optoelectronic characterization.** After guided growth of the ZnSe  
50  
51 core, the sample was removed from the growth reactor. A photolithography mask compatible  
52  
53 with the catalyst pattern was used to define 0.01 mm<sup>2</sup> squares that for the 200 nm SiO<sub>2</sub> protective  
54  
55 layer that was deposited using e-beam deposition. The samples were cleaned in Acetone, IPA  
56  
57  
58  
59  
60

1  
2  
3 and DI water before they were dried in N<sub>2</sub> and inserted into a clean reactor for the ZnTe shell  
4  
5 growth. The shell growth is as described above with a prior step where the samples were heated  
6  
7 at 730°C for 1 min in the 2% H<sub>2</sub> in N<sub>2</sub> atmosphere to remove oxides that could form between the  
8  
9 two crystal growth steps. After the shell growth the protective layer was etched in 6:1 buffered  
10  
11 oxide etch. Ti/Au (10/90 nm) source/drain electrodes were patterned using photolithography and  
12  
13 deposited over the shell and core of the guided nanowires, separated by 2 or 8 μm gaps.  
14  
15 Optoelectronic measurements were done under vacuum at room temperature using a Janis ST-  
16  
17 500 probe system with a Keithley 4200-SCS. The electrical measurements were done in dark  
18  
19 condition (16 μW/cm<sup>2</sup> ambient light). For optoelectronic measurements we used a 405 nm laser  
20  
21 diode module (Laser Components) to illuminate the device with power controlled by a metallic  
22  
23 neutral density filter (Thorlabs). The light intensity was calibrated with a LM-2 VIS silicon  
24  
25 photodiode optical sensor (Coherent).
