ABSTRACT

Background

The projected rise in the incidence of type 2 diabetes mellitus (T2DM) could develop into a substantial health problem worldwide. Whether diet, physical activity or both can prevent or delay T2DM and its associated complications in at-risk people is unknown.

Objectives

To assess the effects of diet, physical activity or both on the prevention or delay of T2DM and its associated complications in people at increased risk of developing T2DM.

Search methods

This is an update of the Cochrane Review published in 2008. We searched the CENTRAL, MEDLINE, Embase, ClinicalTrials.gov, ICTRP Search Portal and reference lists of systematic reviews, articles and health technology assessment reports. The date of the last search of all databases was January 2017. We continuously used a MEDLINE email alert service to identify newly published studies using the same search strategy as described for MEDLINE up to September 2017.

Selection criteria

We included randomised controlled trials (RCTs) with a duration of two years or more.

Data collection and analysis

We used standard Cochrane methodology for data collection and analysis. We assessed the overall quality of the evidence using GRADE.

Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus (Review)

Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Main results

We included 12 RCTs randomising 5238 people. One trial contributed 41% of all participants. The duration of the interventions varied from two to six years. We judged none of the included trials at low risk of bias for all 'Risk of bias' domains.

Eleven trials compared diet plus physical activity with standard or no treatment. Nine RCTs included participants with impaired glucose tolerance (IGT), one RCT included participants with IGT, impaired fasting blood glucose (IFG) or both, and one RCT included people with fasting glucose levels between 5.3 to 6.9 mmol/L. A total of 12 deaths occurred in 2049 participants in the diet plus physical activity groups compared with 10 in 2050 participants in the comparator groups (RR 1.12, 95% CI 0.50 to 2.50; 95% prediction interval 0.44 to 2.88; 4099 participants, 10 trials; very low-quality evidence). The definition of T2DM incidence varied among the included trials. Altogether 315 of 2122 diet plus physical activity participants (14.8%) developed T2DM compared with 614 of 2389 comparator participants (25.7%) (RR 0.57, 95% CI 0.50 to 0.64; 95% prediction interval 0.50 to 0.65; 4511 participants, 11 trials; moderate-quality evidence). Two trials reported serious adverse events. In one trial no adverse events occurred. In the other trial one of 51 diet plus physical activity participants compared with none of 51 comparator participants experienced a serious adverse event (low-quality evidence). Cardiovascular mortality was rarely reported (four of 1626 diet plus physical activity participants and four of 1637 comparator participants (the RR ranged between 0.94 and 3.16; 3263 participants, 7 trials; very low-quality evidence). Only one trial reported that no non-fatal myocardial infarction or non-fatal stroke had occurred (low-quality evidence). Two trials reported that none of the participants had experienced hypoglycaemia. One trial investigated health-related quality of life in 2144 participants and noted that a minimal important difference between intervention groups was not reached (very low-quality evidence). Three trials evaluated costs of the interventions in 2755 participants. The largest trial of these reported an analysis of costs from the health system perspective and society perspective reflecting USD 31,500 and USD 51,600 per quality-adjusted life year (QALY) with diet plus physical activity, respectively (low-quality evidence). There were no data on blindness or end-stage renal disease.

One trial compared a diet-only intervention with a physical-activity intervention or standard treatment. The participants had IGT. Three of 130 participants in the diet group compared with none of the 141 participants in the physical activity group died (very low-quality evidence). None of the participants died because of cardiovascular disease (very low-quality evidence). Altogether 57 of 130 diet participants (43.8%) compared with 58 of 141 physical activity participants (41.1%) group developed T2DM (very low-quality evidence). No adverse events were recorded (very low-quality evidence). There were no data on non-fatal myocardial infarction, non-fatal stroke, blindness, end-stage renal disease, health-related quality of life or socioeconomic effects.

Two trials compared physical activity with standard treatment in 397 participants. One trial included participants with IGT, the other trial included participants with IGT, IFG or both. One trial reported that none of the 141 physical activity participants compared with three of 133 control participants died. The other trial reported that three of 84 physical activity participants and one of 39 control participants died (very low-quality evidence). In one trial T2DM developed in 58 of 141 physical activity participants (41.1%) compared with 90 of 133 control participants (67.7%). In the other trial 10 of 84 physical activity participants (11.9%) compared with seven of 39 control participants (18%) developed T2DM (very low-quality evidence). Serious adverse events were rarely reported (one trial noted no events, one trial described events in three of 66 physical activity participants compared with one of 39 control participants - very low-quality evidence). Only one trial reported on cardiovascular mortality (none of 274 participants died - very low-quality evidence). Non-fatal myocardial infarction or stroke were rarely observed in the one trial randomising 123 participants (very low-quality evidence). One trial reported that none of the participants in the trial experienced hypoglycaemia. One trial investigating health-related quality of life in 123 participants showed no substantial differences between intervention groups (very low-quality evidence). There were no data on blindness or socioeconomic effects.

Authors' conclusions

There is no firm evidence that diet alone or physical activity alone compared to standard treatment influences the risk of T2DM and especially its associated complications in people at increased risk of developing T2DM. However, diet plus physical activity reduces or delays the incidence of T2DM in people with IGT. Data are lacking for the effect of diet plus physical activity for people with intermediate hyperglycaemia defined by other glycaemic variables. Most RCTs did not investigate patient-important outcomes.

PLAIN LANGUAGE SUMMARY

Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk

Review question

Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus (Review) 2

Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Are diet or physical activity, or both able to prevent or delay the development of type 2 diabetes and its associated complications in at-risk people?

Background

People with moderately elevated blood glucose (often referred to as 'prediabetes') are said to be at an increased risk of developing type 2 diabetes. It is currently recommended that all people with increased risk of developing type 2 diabetes should adjust their eating habits and physical activity levels. We wanted to find out whether these changes in diet, physical activity or both could prevent or delay type 2 diabetes in people at increased risk. We also wanted to know the effects on patient-important outcomes, such as complications of diabetes (e.g. kidney and eye disease, heart attack, stroke), death from any cause, health-related quality of life (a measure of a person's satisfaction with their life and health) and side-effects.

Study characteristics

Participants had to have blood glucose levels higher than considered normal, but below the glucose levels that are used to diagnose type 2 diabetes mellitus. We found 12 randomised controlled trials (clinical studies where people are randomly put into one of two or more treatment groups) with 5238 participants. The duration of the treatments varied from two years to six years. Most trials included people defined as being at increased risk of type 2 diabetes based on glucose levels measured two hours after ingestion of 75 g of glucose (i.e. 'impaired glucose tolerance' (IGT) after an oral glucose tolerance test).

This evidence is up to date as of January 2017. We used a MEDLINE email alert service to identify newly published studies up to September 2017.

Key results

One study compared diet only with physical activity only. Fifty-seven of 130 participants (44%) in the diet-only group compared with 58 of 141 participants (41%) in the physical activity-only group developed type 2 diabetes. Two studies compared physical activity with standard treatment; in one study 58 of 141 participants (41%) in the physical activity group compared with 90 of 133 participants (68%) in the control group developed type 2 diabetes; in the other study 10 of 84 participants (12%) in the physical activity group compared with seven out of 39 participants (18%) in the control group developed type 2 diabetes. Eleven studies compared diet plus physical activity with standard or no treatment. Diet plus physical activity decreased the risk of developing type 2 diabetes, which occurred in 315 of 2122 participants (15%) in the diet plus physical activity group compared with 614 of 2389 participants (26%) in the standard treatment group.

We detected neither an advantage nor a disadvantage of diet, physical activity or both with regard to heart attacks or strokes. Our included studies did not report on complications of diabetes such as kidney or eye disease. The effects on health-related quality of life were inconclusive. Very few participants died in the course of the studies and side-effects were also rare. Future long-term studies should investigate more patient-important outcomes like complications of diabetes, because we do not know for sure whether 'prediabetes' is just a condition arbitrarily defined by a laboratory measurement or is, in fact, a real risk factor for type 2 diabetes mellitus and whether treatment of this condition translates into better patient-important outcomes.

Quality of the evidence

All included trials had deficiencies in the way that they were conducted or how key items were reported. For diet plus physical activity compared with standard treatment, we found rather good evidence that the development of new type 2 diabetes was reduced or delayed. For the other comparisons the number of participants was small, resulting in a high risk of random errors (play of chance).

SUMMARY OF FINDINGS FOR THE MAIN COMPARISON *[Explanation]*

Diet plus physical activity versus standard treatment for prevention or delay of type 2 diabetes mellitus						
Population: people at increased risk of developing type 2 diabetes mellitus Settings: outpatients Intervention: diet plus physical activity Comparison: standard treatment						
Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of participants (trials)	Quality of the evidence (GRADE)	Comments
	Standard treatment	Diet plus physical activity				
All-cause mortality Follow-up: up to 6 years (mean duration 3.6 years)	5 per 1000	5 per 1000 (2 to 12)	RR 1.12 (0.50 to 2.50)	4099 (10)	⊕○○○ very low ^a	The 95% prediction interval ranged from 0.44 to 2.88 TSA showed that 0.61% of the diversity-adjusted information size was accrued to detect or reject a 10% RRR

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

ADA: American Diabetes Association; **CI:** confidence interval; **DPP:** Diabetes Prevention Program; **FGL:** fasting glucose levels; **FPG:** fasting plasma glucose; **MCS:** mental component summaries; **MID:** minimal important difference; **OGTT:** oral glucose tolerance test; **PCS:** physical component summaries; **PG:** plasma glucose; **QUALY:** quality-adjusted life years; **RR:** risk ratio; **RRR:** relative risk reduction; **SAE:** serious adverse event; **SF-36:** 36-Item Short-Form; **SF-6D:** health utility index (SF-6D); **T2DM:** type 2 diabetes mellitus; **TSA:** trial sequential analysis; **WHO:** World Health Organization

GRADE Working Group grades of evidence

High quality: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate quality: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of effect, but there is a possibility that it is substantially different.

Low quality: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of effect, but there is a possibility that it is substantially different.

Very low quality: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect

*Assumed risk was derived from the event rates in the comparator groups

^aDowngraded by three levels because of risk of bias including possible publication and other bias, inconsistency and imprecision - see [Appendix 14](#).

^bDowngraded by one level because of other bias (early termination of three trials due to benefit providing the majority of data) - see [Appendix 14](#).

^cDowngraded by two levels because of reporting bias and imprecision - see [Appendix 14](#).

^dDowngraded by two levels because of serious imprecision (very sparse data) - see [Appendix 14](#).

^eDowngraded by three levels because of serious risk of bias (performance bias, detection bias, other bias) and imprecision - see [Appendix 14](#).

^fDowngraded by two levels because of risk of bias (trial stopped early for benefit providing the majority of data) and imprecision - see [Appendix 14](#).

BACKGROUND

Description of the condition

'Prediabetes', 'borderline diabetes', the 'prediabetic stage', 'high risk of diabetes' or 'intermediate hyperglycaemia' (WHO/IDF 2006) are often characterised by various measurements of elevated blood glucose concentrations (such as isolated impaired fasting glucose (IFG), isolated impaired glucose tolerance (IGT), isolated elevated glycosylated haemoglobin A1c (HbA1c) or combinations thereof). These elevated blood glucose levels indicating hyperglycaemia are considered too high to be normal but below the diagnostic threshold for type 2 diabetes mellitus (T2DM). Therefore, because of the continuous spectrum from the normal to the diabetic stage, a sound evidence base is needed to define thresholds for conditions of 'sub-diabetes'. It is obvious that the different terms used to describe various stages of hyperglycaemia might induce different emotional reactions. For example, the term 'prediabetes' may imply (at least for the lay person) that diabetes is unavoidable whereas (high) risk of diabetes has the positive connotation that the disease may be avoided altogether. We will use all of the above-mentioned terms throughout this systematic review, however we will focus on 'prediabetes' because many people associate this label with dire consequences - despite the disputable construct of intermediate health states termed prediseases (Viera 2011). On the other side, any diagnosis of 'prediabetes' might be an opportunity to review, for example, eating habits and physical activity levels, thus enabling affected individuals to actively change their way of life.

The most commonly used criteria to define people with a high risk of developing T2DM were established by the American Diabetes Association (ADA) and the World Health Organization (WHO). The first glycaemic measurement used to define the prediabetic stage by the US National Diabetes Data Group was IGT (NDDG 1979). IGT is based on the measurement of plasma glucose two hours after ingestion of 75 g glucose. The prediabetic range is defined as a plasma glucose level between 7.8 to 11.1 mmol/L (140 to 200 mg/dL) two hours after the glucose load. Studies have indicated that IGT is caused by insulin resistance and defective insulin secretion (Abdul-Ghani 2006). In 1997 the ADA and later on the WHO introduced the IFG concept to define 'prediabetes' (ADA 1997; WHO 1999). The initial definition of IFG was 6.1 to 6.9 mmol/L (110 to 125 mg/dL). Later on, the ADA reduced the lower threshold for defining IFG to 5.6 mmol/L (100 mg/dL) (ADA 2003). However, this lower cut-off point for IFG to define 'prediabetes' was not endorsed by the WHO (WHO/IDF 2006). IFG seems to be associated with β -cell dysfunction (impaired insulin secretion) and an increase of the hepatic glucose output (DeFronzo 1989). More recently, HbA1c has been introduced for identifying people with a high risk of developing T2DM. In 2009, the International Expert Committee (IEC) suggested the HbA1c to identify people with a high risk of T2DM. People with HbA1c

measurements between 6.0% to 6.4% fulfilled this criterion (IEC 2009). Shortly after, the ADA redefined this HbA1c level as 5.7% to 6.4% to identify people with a high risk of developing T2DM (ADA 2010). Unlike IFG and IGT, HbA1c reflects longer-term glycaemic control, that is, how the blood glucose levels have been during the previous two to three months (Inzucchi 2012).

In 2010, the International Diabetes Federation (IDF) estimated the prevalence of IGT to be 343 million, and this number is predicted to increase to 471 million by 2035 (IDF 2013). Studies have shown poor correlations between HbA1c and IFG/IGT (Gosmanov 2014; Selvin 2011). Moreover, the various glycaemic tests do not seem to identify the same people (Gosmanov 2014; Selvin 2011). The risk of progression from 'prediabetes' to T2DM depends on the diagnostic criteria used to identify 'prediabetes'. Some people diagnosed with 'prediabetes' will never develop T2DM, and some will return to normoglycaemia. IGT is often accepted as the best glycaemic variable for 'prediabetes' to predict progression to T2DM. However, studies indicate that less than half of the people defined as prediabetic by means of IGT will develop T2DM in the following 10 years. IFG and HbA1c are both thought to predict a different risk spectrum for developing T2DM (Cheng 2006; Morris 2013). Most importantly, 'prediabetes' is commonly an asymptomatic condition, and naturally often remains 'undiagnosed' (CDC 2015). Consequently, 'prediabetes' may exist before the diagnosis of T2DM is established.

Currently, ADA recommends reduced calorie intake and increased physical activity for people with increased risk of T2DM (ADA 2017). It is still not clarified if any particular intervention, especially glucose-lowering drugs, should be recommended for people with 'prediabetes' (Yudkin 2014). Trials have indicated that the progression from 'prediabetes' to T2DM is reduced, or maybe just delayed with 'lifestyle' interventions (increased physical activity, dietary changes or both) (Diabetes Prevention Program 2002; Diabetes Prevention Program FU 2009; Finnish Diabetes Prevention Study Group 2001). A recent meta-analysis of 22 studies with behaviour-changing interventions in people at high risk of T2DM concluded that the effect of lifestyle interventions on longer-term diabetes prevention had not been clarified (Dunkley 2014).

The prescription of pharmacological glucose-lowering interventions for the prevention of T2DM is not generally accepted among international diabetes associations and clinicians. Several groups of pharmacological glucose-lowering interventions have been investigated in people with 'prediabetes'. Some findings indicate that the progression from 'prediabetes' to T2DM is reduced or maybe just delayed (Diabetes Prevention Program 2002; Diabetes Prevention Program FU 2009). However, the ADA recommends metformin for people with 'prediabetes' and a body mass index more than 35 kg/m², aged less than 60 years, and women with prior gestational diabetes mellitus (ADA 2015).

Description of the intervention

Interventional as well as observational studies have shown a reduction in the incidence of T2DM with reduced calorie intake and increased physical activity in people at risk of T2DM (Da Qing 1997; DPP 2002; Helmrigh 1991; Smith 2016). It has been shown that diet plus physical activity reduces cardiovascular risk factors, thereby indicating a potential beneficial effect on mortality and cardiovascular outcomes (Balk 2015).

Diet plus physical activity is recommended as an initial intervention not only for people with intermediate hyperglycaemia but also for people with T2DM (ADA 2017). However, one large-scale, randomised, controlled trial in people overweight or obese people with T2DM did not show a substantial effect on mortality and cardiovascular outcomes with intensive diet plus physical activity compared with control after 9.6 years (Look AHEAD 2013).

Nutritional advice usually consists of caloric restriction in overweight people, low total fat content (especially saturated fat) and high (predominantly unrefined) carbohydrate content. Physical activity advice usually consists of an intervention programme.

Adverse effects of the intervention

Physical activity or diet interventions are not generally considered to be associated with any serious adverse event. However, physical activity may cause traumatic injuries of variable severity depending on the type and intensity of physical activity. Additionally, exercising may produce adverse effects on the cardiovascular system in those people with insufficient training or unfavourable cardiovascular fitness (even cardiovascular events and death may potentially occur while exercising). Also, the implementation of dietary measures may produce several deficiencies in nutritional status if restrictive low-calorie diets are used. Further, dieting may reduce quality of life of people under this treatment. Unfortunately, very little information on these issues is available from randomised controlled trials.

How the intervention might work

There are prospective cohort studies that have shown that increased physical activity, independent of other risk factors, has a protective effect against the development of T2DM (Helmrigh 1991; Manson 1992). These epidemiological prospective studies demonstrated that various levels of regular physical activity once to several times a week were associated with a decreased incidence of the disease at long-term follow-up (14 years and five years respectively) (Helmrigh 1991; Manson 1992).

Three large clinical trials in people with IGT have shown a relative risk reduction of about 50% in the progression to T2DM with restricted diet and increased physical activity (Da Qing 1997; DPP 2002; DPS 2001). However, whether and how diet, physical activity or both influence the risk of complications associated with T2DM is still not clarified.

Why it is important to do this review

There has been an increased focus on the prevention or delay of T2DM with non-pharmacological interventions and glucose-lowering medications. Recently, several systematic reviews and health technology assessment reports have been performed in people with elevated risk of T2DM (Aguiar 2014; Ali 2012; Ashra 2015; Balk 2015; Cardona-Morrell 2010; Dunkley 2014; Gillett 2012; Gillies 2007; Glechner 2015; Gong 2015; Hopper 2011; ICER 2016; Merlotti 2014a; Merlotti 2014b; Modesti 2016; Norris 2005; Santaguida 2005; Schellenberg 2013; Selph 2015; Stevens 2015; Yamaoka 2005; Yates 2007; Yoon 2013; Yuen 2010; Zhang 2017; Zheng 2016).

Sixteen of these systematic reviews included exclusively people with intermediate hyperglycaemia (Aguiar 2014; Gillett 2012; Gillies 2007; Glechner 2015; Gong 2015; Hopper 2011; ICER 2016; Norris 2005; Santaguida 2005; Selph 2015; Stevens 2015; Yamaoka 2005; Yates 2007; Yoon 2013; Yuen 2010; Zheng 2016); 10 systematic reviews included people with an increased risk of T2DM defined by additional variables with intermediate hyperglycaemia being one risk factor only (e.g. obesity, metabolic risk factors, family history of diabetes etc) (Ali 2012; Ashra 2015; Balk 2015; Cardona-Morrell 2010; Dunkley 2014; Merlotti 2014a; Merlotti 2014b; Modesti 2016; Schellenberg 2013; Zhang 2017). This review is an update of the Cochrane Review published in 2008 (Orozco 2008). In this update we have implemented new methodology and changed the priority of outcomes, focusing on patient-important outcome measures. Also, we have only included trials where intermediate hyperglycaemia was measured at baseline as an indicator of increased risk for the development of T2DM.

OBJECTIVES

To assess the effects of diet, physical activity or both for the prevention or delay of T2DM and its associated complications in people at increased risk of developing T2DM.

METHODS

Criteria for considering studies for this review

Types of studies

We included randomised controlled clinical trials (RCTs).

Types of participants

Nondiabetic individuals at increased risk of developing T2DM, that is, diagnosed with intermediate hyperglycaemia or 'prediabetes'.

Diagnostic criteria for 'prediabetes'

To be consistent with changes in the classification of and diagnostic criteria for 'prediabetes' (impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and elevated glycosylated haemoglobin A1c (HbA1c)) over the years, the diagnosis had to be established using the standard criteria valid at the time of the trial commencing (for example [ADA 1997](#); [ADA 2010](#); [NDDG 1979](#); [WHO 1999](#)). Ideally, the diagnostic criteria should have been described. If necessary, we used the trial authors' definition of 'prediabetes' but contacted trial authors for additional information. Differences of glycaemic measurements used to define 'prediabetes' may introduce substantial heterogeneity. We therefore planned to subject diagnostic criteria to a subgroup analysis.

Types of interventions

We planned to investigate the following comparisons of intervention versus comparator.

Intervention

- Diet
- Physical activity
- Diet plus physical activity

Comparator

- Standard treatment
- No intervention

Comparison of interventions

- Diet versus physical activity

Other concomitant interventions had to be the same in the intervention and comparator groups to establish fair comparisons.

Minimum duration of intervention

We included trials with a minimum duration of intervention of two years.

Summary of exclusion criteria

We excluded the following.

- Trials where the intervention or comparator group comprised the administration of any pharmacological agent.
- People diagnosed with 'metabolic syndrome' because this is a special cohort of doubtful clinical usefulness and uncertain distinct disease entity (a composite of risk indicators such as elevated blood lipids, insulin resistance, obesity, high blood pressure).
- Trials applying diet advice through single-food or supplement dietary changes (e.g. zinc supplement).
- Trials with identical diet or physical activity interventions, or both, applied with different approaches (e.g. same advice applied by means of individual or group sessions).

We did not exclude trials because one or several of our primary or secondary outcome measures were not reported in the publication. In case none of our primary or secondary outcomes were reported, we included the trial and contacted the corresponding author for supplementary data. If no additional data were available we planned to provide some basic information in a supplementary table.

Types of outcome measures

Primary outcomes

- All-cause mortality
- Incidence of T2DM
- Serious adverse events

Secondary outcomes

- Cardiovascular mortality
- Non-fatal myocardial infarction
- Non-fatal stroke
- Amputation of lower extremity
- Blindness or severe vision loss
- End-stage renal disease
- Non-serious adverse events
- Hypoglycaemia
- Health-related quality of life
- Time to progression to T2DM
- Measures of blood glucose control
- Socioeconomic effects

Method of outcome measurement

- All-cause mortality: defined as death from any cause
- Incidence of T2DM and time to progression to T2DM: defined according to diagnostic criteria valid at the time the diagnosis was established, using the standard criteria valid at the time of the trial commencing (e.g. [ADA 2008](#); [WHO 1998](#)). If necessary, we used the trial authors' definition of T2DM.
 - Serious adverse events: defined according to the International Conference on Harmonization Guidelines as any event that led to death, that was life-threatening, required in-patient hospitalisation or prolongation of existing hospitalisation, resulted in persistent or significant disability, and any important medical event that may have had jeopardised the participant or required intervention to prevent it ([ICH 1997](#)) or as reported in trials.
 - Cardiovascular mortality, non-fatal myocardial infarction, non-fatal stroke, amputation of lower extremity, blindness or severe vision loss, hypoglycaemia (mild, moderate, severe/serious): defined as reported in trials.
 - End-stage renal disease: defined as dialysis, renal transplantation or death due to renal disease.

- Non-serious adverse events: defined as number of participants with any untoward medical occurrence not necessarily having a causal relationship with the intervention.
- Health-related quality of life: defined as mental and physical health-related quality of life, separate and combined, evaluated by a validated instrument such as Short-Form 36.
- Measures of blood glucose control: fasting blood glucose, blood glucose two hours after ingestion of 75 g glucose and HbA1c measurements.
- Socioeconomic effects: for example costs of the intervention, absence from work, medication consumption.

Timing of outcome measurement

- Measured at the end of the intervention and the end of follow-up: all-cause mortality, cardiovascular mortality, blindness or severe vision loss, hypoglycaemia (mild, moderate, severe/serious), end-stage renal disease, non-serious adverse events; health-related quality of life, measures of blood glucose control, socioeconomic effects
- Measured at the end of the intervention and the longest reported end of follow-up: incidence of T2DM
- Measured at any time of the intervention and during follow-up: serious adverse events

Search methods for identification of studies

Electronic searches

We based this review update on different search techniques. First, we extracted the included trials of two systematic reviews targeting people at increased risk for T2DM. The first review was funded by the Agency for Healthcare Research and Quality (AHRQ) and evaluated lifestyle interventions (Schellenberg 2013). The second review was funded by the Centers for Disease Control and Prevention Community Preventive Services Task Force and evaluated combined diet and physical activity programs (Balk 2015). Both of these reviews included extensive and highly sensitive search strategies conducted in several databases up to June 2013 (Schellenberg 2013) and up to February 2015 (Balk 2015). In addition to evaluating these two systematic reviews, we checked the reference lists of a further 28 systematic reviews and extracted 145 potentially relevant trials in total. This snowballing search technique is reflected in the upper right part of the trial flow diagram.

Second, we identified further trials using a revised search strategy from 2014 to the specified date. We did not place restrictions on the language of publication, and searched the following literature databases.

- Cochrane Central Register of Controlled Trials (CENTRAL) via Cochrane Register of Studies Online (CRSO) (searched 17 January 2017).
- MEDLINE Ovid (Epub Ahead of Print, In-Process & Other Non-Indexed Citations, Ovid MEDLINE(R) Daily and Ovid MEDLINE(R)) (from 1946 to present, searched 17 January 2017).
- Embase Ovid (from 1974 to 2017 Week 3, searched 17 January 2017)

Additionally we searched the following trials registers from inception to the specified date.

- ClinicalTrials.gov (www.clinicaltrials.gov) (searched 17 January 2017).
- WHO International Clinical Trials Registry Platform (ICTRP; apps.who.int/trialsearch/) searched 17 January 2017)

For detailed search strategies, see Appendix 1. We continuously applied an email alert service for MEDLINE via OvidSP to identify newly published trials using the search strategy detailed in Appendix 1 up to September 2017.

Searching other resources

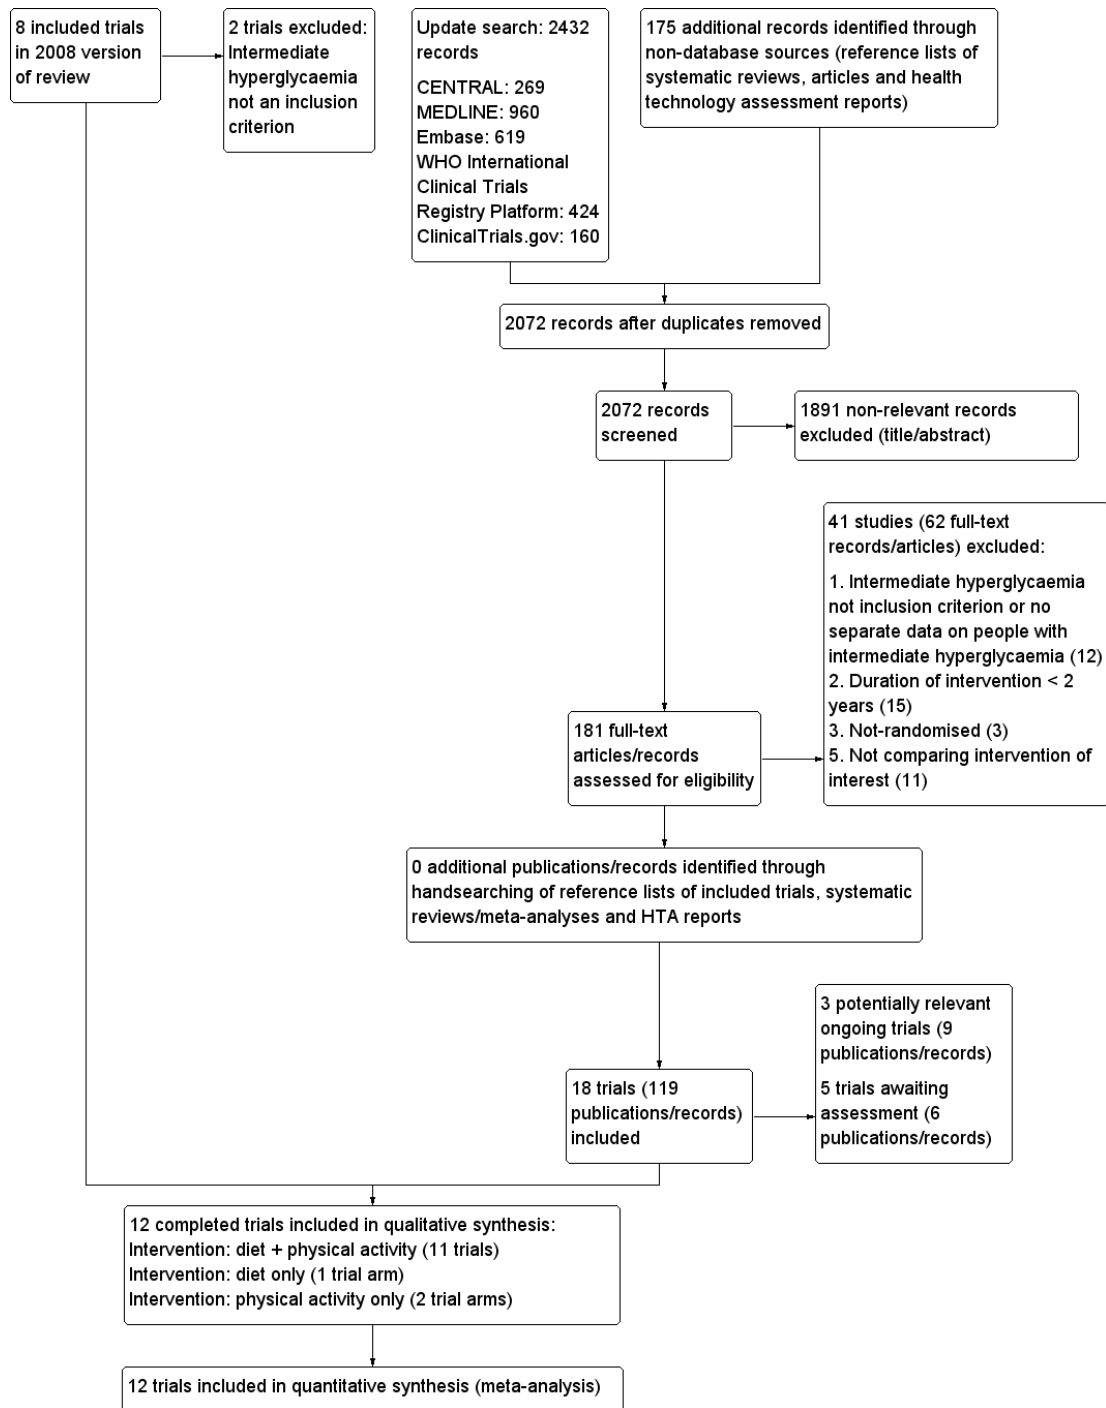

We tried to identify other potentially eligible trials or ancillary publications by searching the reference lists of retrieved, included trials, (systematic) reviews, meta-analyses and health technology assessment reports.

Data collection and analysis

Selection of studies

Two review authors (BH and BR) independently scanned the abstract or title, or both, of every record we retrieved, to determine which trials should be assessed further. We investigated the full-text articles of all potentially relevant articles. We resolved discrepancies through consensus or by recourse to a third review author (MM). We prepared a flow diagram of the number of trials identified and excluded at each stage in accordance with the PRISMA flow diagram of trial selection (Liberati 2009; Figure 1).

Figure I. Trial flow diagram

Data extraction and management

For trials that fulfilled the inclusion criteria, two review authors (BH and GG) independently extracted outcome data and assessed the risk of bias. One review author (BH) extracted key characteristics of participants and interventions and another (GG) checked them. We reported data on efficacy outcomes and adverse events using standard data extraction sheets from Cochrane Metabolic and Endocrine Disorders. We resolved any disagreements by discussion or, if required, by consultation with a third review author (BR) (for details, see [Characteristics of included studies](#); [Table 1](#); [Appendix 2](#); [Appendix 3](#); [Appendix 4](#); [Appendix 5](#); [Appendix 6](#); [Appendix 7](#); [Appendix 8](#); [Appendix 9](#); [Appendix 10](#); [Appendix 11](#); [Appendix 12](#); [Appendix 13](#); [Appendix 14](#); [Appendix 15](#); [Appendix 16](#); [Appendix 17](#); [Appendix 18](#); [Appendix 19](#)).

We provided information about potentially relevant ongoing trials, including trial identifier, in the '[Characteristics of ongoing studies](#)' table and in a joint appendix 'Matrix of study endpoints (publications and trial documents)' ([Appendix 6](#)). For each included trial, we tried to retrieve the protocol and planned to report primary, secondary and other outcomes in comparison with data in publications in a joint appendix. If not available from the search of the databases, reference screening or Internet searches, we asked trial authors to provide a copy of the protocol.

We emailed all authors of the included trials to enquire whether they would be willing to answer questions regarding their trials. We presented the results of this survey in [Appendix 13](#). We sought relevant missing information on the trial from the primary author(s) of the article, if possible.

Dealing with duplicate and companion publications

In the event of duplicate publications, companion documents, or multiple reports of a primary trial, we maximised the information yield by collating all available data, and we used the most complete data set aggregated across all known publications. We listed duplicate publications, companion documents, multiple reports of a primary trial, and trial documents of included trials (such as trial registry information) as secondary references under the study ID of the included trial. Furthermore, we also listed duplicate publications, companion documents, multiple reports of a trial, and trial documents of excluded trials (such as trials registry information) as secondary references under the study ID of the excluded trial.

Data from clinical trials registers

If data from included trials were available as study results in clinical trials registers, such as [ClinicalTrials.gov](#) or similar sources, we made full use of this information and extracted the data. If there was also a full publication of the trial, we collated and critically appraised all available data. If an included trial was marked as a completed study in a clinical trials register but no additional

information (study results, publication or both) was available, we added this trial to the table '[Characteristics of studies awaiting classification](#)'.

Assessment of risk of bias in included studies

Two review authors (BH and GG) independently assessed the risk of bias of each included trial. We resolved any disagreements by consensus, or by consultation with a third review author (BR). If adequate information was not available from the trial publication, trial protocol or both, we contacted trial authors for missing data on 'Risk of bias' items.

We used the Cochrane 'Risk of bias' assessment tool ([Higgins 2011a](#)) and judged risk of bias criteria as either low, high, or unclear and evaluated individual bias items as described in the *Cochrane Handbook for Systematic Reviews of Interventions* ([Higgins 2011a](#)) where any of the specified criteria for a judgement on low, unclear or high risk of bias justified the associated categorisation.

Random sequence generation

Selection bias due to inadequate generation of a randomised sequence - assessment at trial level

We described for each included trial the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

- Low risk of bias: sequence generation was achieved using computer random number generation or a random number table. Drawing of lots, tossing a coin, shuffling cards or envelopes, and throwing dice are adequate if performed by an independent person not otherwise involved in the trial. Use of the minimisation technique will be considered as equivalent to being random.
- Unclear risk of bias: insufficient information about the sequence generation process.

- High risk of bias: the sequence generation method was non-random (e.g. sequence generated by odd or even date of birth; sequence generated by some rule based on date (or day) of admission; sequence generated by some rule based on hospital or clinic record number; allocation by judgement of the clinician; allocation by preference of the participant; allocation based on the results of a laboratory test or a series of tests; allocation by availability of the intervention). We excluded such trials.

Allocation concealment

Selection bias due to inadequate concealment of allocations prior to assignment - assessment at trial level

We described for each included trial the method used to conceal allocation to interventions prior to assignment and assessed whether intervention allocation could have been foreseen in advance of, or during recruitment, or changed after assignment.

- Low risk of bias: central allocation (including telephone, interactive voice-recorder, web-based and pharmacy-controlled randomisation); sequentially numbered drug containers of identical appearance; sequentially numbered, opaque, sealed envelopes.

- Unclear risk of bias: insufficient information about the allocation concealment.

- High risk of bias: using an open random allocation schedule (e.g. a list of random numbers); using assignment envelopes without appropriate safeguards; alternation or rotation; date of birth; case record number; any other explicitly unconcealed procedure. We excluded such trials.

Blinding of participants and study personnel

Performance bias due to knowledge of the allocated interventions by participants and personnel during the trial - assessment at outcome level

We evaluated the risk of performance bias separately for each outcome (Hróbjartsson 2013). We noted whether outcomes were self-reported, investigator-assessed or adjudicated outcome measures (see below).

- Low risk of bias: blinding of participants and key study personnel ensured, and unlikely that the blinding could have been broken; no blinding or incomplete blinding, but the review authors judged that the outcome was not likely to be influenced by lack of blinding.

- Unclear risk of bias: insufficient information about the blinding of participants and study personnel; the trial did not address this outcome.

- High risk of bias: no blinding or incomplete blinding, and the outcome was likely to be influenced by lack of blinding; blinding of trial participants and key personnel attempted, but likely that the blinding could have been broken, and the outcome was likely to be influenced by lack of blinding.

Blinding of outcome assessment

Detection bias due to knowledge of the allocated interventions by outcome assessment - assessment at outcome level

We evaluated the risk of detection bias separately for each outcome (Hróbjartsson 2013). We noted whether outcomes were self-reported, investigator-assessed or adjudicated outcome measures (see below).

- Low risk of bias: blinding of outcome assessment ensured, and unlikely that the blinding could have been broken; no blinding of outcome assessment, but the review authors judged that the outcome measurement was not likely to be influenced by lack of blinding.

- Unclear risk of bias: insufficient information about the blinding of outcome assessors; the trial did not address this outcome.

- High risk of bias: no blinding of outcome assessment, and the outcome measurement is likely to be influenced by lack of blinding; blinding of outcome assessment, but likely that the

blinding could have been broken, and the outcome measurement is likely to be influenced by lack of blinding.

Incomplete outcome data

Attrition bias due to amount, nature or handling of incomplete outcome data - assessment at outcome level

We described for each included trial, and for each outcome, the completeness of data including attrition and exclusions from the analysis. We investigated whether attrition and exclusions were reported and the number included in the analysis at each stage (compared with the number of randomised participants per intervention/comparator groups), if reasons for attrition or exclusion were reported, and whether missing data were balanced across groups or were related to outcomes. We considered the implications of missing outcome data per outcome, such as high dropout rates (e.g. above 15%) or disparate attrition rates (e.g. difference of 10% or more between trial arms).

- Low risk of bias: no missing outcome data; reasons for missing outcome data unlikely to be related to true outcome (for survival data, censoring unlikely to be introducing bias); missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups; for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk not enough to have a clinically relevant impact on the intervention effect estimate; for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes not enough to have a clinically relevant impact on observed effect size; appropriate methods, such as multiple imputation, were used to handle missing data.

- Unclear risk of bias: insufficient information to assess whether missing data in combination with the method used to handle missing data were likely to induce bias; the trial did not address this outcome.

- High risk of bias: reason for missing outcome data likely to be related to true outcome, with either imbalance in numbers or reasons for missing data across intervention groups; for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk enough to induce clinically relevant bias in intervention effect estimate; for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes enough to induce clinically relevant bias in observed effect size; 'as-treated' or similar analysis done with substantial departure of the intervention received from that assigned at randomisation; potentially inappropriate application of simple imputation.

Selective reporting

Reporting bias due to selective outcome reporting - assessment at trial level

We assessed outcome reporting bias by integrating the results of Appendix 6, 'Matrix of trial endpoints (publications and trial documents)' (Mathieu 2009), with those of Appendix 7 'High

risk of outcome reporting bias according to ORBIT classification' (Kirkham 2010). This analysis formed the basis for the judgement of selective reporting.

- Low risk of bias: the trial protocol was available and all of the trial's pre-specified (primary and secondary) outcomes that were of interest in the review were reported in the pre-specified way; the study protocol was not available but it was clear that the published reports included all expected outcomes (ORBIT classification).

- Unclear risk of bias: insufficient information about selective reporting.

- High risk of bias: not all of the trial's pre-specified primary outcomes were reported; one or more primary outcomes was reported using measurements, analysis methods or subsets of the data (e.g. subscales) that had not been pre-specified; one or more reported primary outcomes had not been pre-specified (unless clear justification for their reporting was provided, such as an unexpected adverse effect); one or more outcomes of interest in the review were reported incompletely so that they could not be entered in a meta-analysis; the trial report failed to include results for a key outcome that would be expected to have been reported for such a trial (ORBIT classification).

Other bias

Bias due to problems not covered elsewhere - assessment at trial level

Other risk of bias reflects other circumstances that may threaten the validity of the trials, for example, funding bias and academic bias (Lundh 2012).

- Low risk of bias: the trial appeared to be free of other sources of bias.

- Unclear risk of bias: insufficient information to assess whether an important risk of bias existed; insufficient rationale or evidence that an identified problem introduced bias.

- High risk of bias: had a potential source of bias related to the specific trial design used; has been claimed to have been fraudulent; had some other serious problem.

We presented a 'Risk of bias' graph and a 'Risk of bias' summary figure.

We distinguished between self-reported, investigator-assessed and adjudicated outcome measures.

We considered the following self-reported outcomes.

- Non-serious adverse events
- Hypoglycaemia, if reported by participants
- Health-related quality of life
- Blood glucose control, if measured by trial participants

We considered the following investigator-assessed outcomes

- All-cause mortality
- Incidence of T2DM
- Time to progression to T2DM
- Serious adverse events
- Cardiovascular mortality

- Non-fatal myocardial infarction
- Non-fatal stroke
- Amputation of lower extremity
- Blindness or severe vision loss
- End-stage renal disease
- Hypoglycaemia, if measured by trial personnel
- Blood glucose control, if measured by trial personnel
- Socioeconomic effects.

Summary assessment of risk of bias

Risk of bias for a trial across outcomes

Some risk of bias domains like selection bias (sequence generation and allocation sequence concealment) affected the risk of bias across all outcome measures in a trial. Otherwise, we did not perform a summary assessment of the risk of bias across all outcomes for a trial. In case of high risk of selection bias, we excluded the trial.

Risk of bias for an outcome within a trial and across domains

We assessed the risk of bias for an outcome measure including all of the entries relevant to that outcome, that is, both trial-level entries and outcome-specific entries. Low risk of bias was defined as low risk of bias for all key domains, unclear risk of bias as unclear risk of bias for one or more key domains and high risk of bias as high risk of bias for one or more key domains.

Risk of bias for an outcome across trials and across domains

These were our main summary assessments that were incorporated in our judgements about the quality of evidence in the 'Summary of finding' table(s). Low risk of bias was defined as most information coming from trials at low risk of bias, unclear risk of bias as most information coming from trials at low or unclear risk of bias and high risk of bias as a sufficient proportion of information coming from trials at high risk of bias.

Measures of treatment effect

When at least two trials were available for a comparison of a given outcome we expressed dichotomous data as risk ratio (RR) with 95% confidence intervals (CIs) and with trial sequential analysis (TSA)-adjusted CIs if the diversity-adjusted required information size was not reached. We planned to calculate time-to-event data as hazard ratio (HR) with 95% CI with the generic inverse variance method. We planned to use unadjusted HRs for preference, as adjustment could differ among the included trials.

We expressed continuous data reported on the same scale as mean difference (MD) with 95% CIs and with TSA-adjusted CIs if the diversity-adjusted required information size was not reached. For

trials addressing the same outcome but using different outcome measure scales we planned to use standardised mean differences (SMD) with 95% CI. For outcomes meta-analysed as SMD and the generic inverse variance method, we are presently unable to conduct TSA and adjust the 95% CIs.

The scales measuring health-related quality of life (HRQoL) may go in different directions. In some scales, values increase with improved HRQoL, whereas in other scales, values decrease with improved HRQoL. To adjust for the different directions of the scales, we planned to multiply the scales that reported better HRQoL with decreasing values by -1.

Unit of analysis issues

We took into account the level at which randomisation occurred, such as cross-over trials, cluster-randomised trials and multiple observations for the same outcome. If more than one comparison from the same trial was eligible for inclusion in the same meta-analysis, we either combined groups to create a single, pairwise comparison or appropriately reduced the sample size so that the same participants did not contribute multiply (splitting the 'shared' group into two or more groups). While the latter approach offers some solution to adjusting the precision of the comparison, it does not account for correlation arising from the same set of participants being in multiple comparisons (Deeks 2011).

We planned to reanalyse cluster-randomised trials that did not appropriately adjust for potential clustering of participants within clusters in their analysis. The variance of the intervention effects would have been inflated by a design effect (DEFF). Calculation of a DEFF involves estimation of an intra-cluster correlation (ICC). We planned to obtain estimates of ICCs through contact with trial authors, or by imputing them using estimates from other included studies that reported ICCs, or using external estimates from empirical research (e.g. Bell 2013). We planned to examine the impact of clustering using sensitivity analyses.

Dealing with missing data

We tried to obtain missing data from trial authors and carefully evaluated important numerical data such as screened, randomly assigned participants as well as intention-to-treat, and as-treated and per-protocol populations.

We investigated attrition rates (e.g. dropouts, losses to follow-up, withdrawals), and critically appraised issues concerning missing data and imputation methods (e.g. last observation carried forward).

Where means and standard deviations (SDs) for outcomes were not reported and we could not get the information that we needed from trial authors, we imputed these values by assuming the SDs of the missing outcome to be the average of the SDs from those trials in which this information was reported.

We planned to investigate the impact of imputation on meta-analyses by performing sensitivity analyses.

Assessment of heterogeneity

In the event of substantial clinical or methodological heterogeneity, we planned not to report trial results as the pooled effect estimate in a meta-analysis.

We identified heterogeneity (inconsistency) by visually inspecting the forest plots and by using a standard χ^2 test with a significance level of $\alpha = 0.1$. In view of the low power of this test, we also considered the I^2 statistic (Higgins 2003), which quantifies inconsistency across trials to assess the impact of heterogeneity on the meta-analysis (Deeks 2011; Higgins 2002).

Assessment of reporting biases

If we included 10 or more trials investigating a particular outcome, we used funnel plots to assess small-trial effects. Several explanations may account for funnel plot asymmetry, including true heterogeneity of effect with respect to trial size, poor methodological design (and hence bias of small trials) and publication bias. We therefore interpreted results carefully (Sterne 2011).

Data synthesis

We planned to undertake (or display) a meta-analysis only if we judged participants, interventions, comparisons, and outcomes to be sufficiently similar to ensure an answer that would be clinically meaningful. Unless good evidence showed homogeneous effects across trials of different methodological quality, we primarily summarised low risk of bias data using a random-effects model (Wood 2008). We interpreted random-effects meta-analyses with due consideration to the whole distribution of effects and presented a 95% prediction interval (Borenstein 2017a; Borenstein 2017b; Higgins 2009). A prediction interval needs at least three trials to be calculated and specifies a predicted range for the true treatment effect in an individual trial (Riley 2011). For rare events such as event rates below 1%, we planned to use the Peto's odds ratio method, provided that there was no substantial imbalance between intervention and comparator group sizes and intervention effects were not exceptionally large. In addition, we performed statistical analyses according to the statistical guidelines presented in the *Cochrane Handbook for Systematic Reviews of Interventions* (Deeks 2011).

Trial sequential analyses

In a single trial, sparse data and interim analyses increase the risk of type I and type II errors. To avoid type I errors, group sequential monitoring boundaries are applied to decide whether a trial could be terminated early because of a sufficiently small P value, that is the cumulative Z-curve crosses the monitoring boundaries (Lan 1983). Likewise, before reaching the planned sample size of a trial, the trial may be stopped due to futility if the cumulative Z-score crosses the futility monitoring boundaries. Sequential monitoring boundaries for benefit, harm, or futility can be applied to meta-analyses as well, called trial sequential monitoring boundaries (

Higgins 2010; Wetterslev 2008). In TSA, the addition of each trial in a cumulative meta-analysis is regarded as an interim meta-analysis and helps to clarify if significance or futility is reached or whether additional trials are needed (Wetterslev 2008).

TSA combines a calculation of the diversity-adjusted required information size (cumulated meta-analysis sample size to detect or reject a specific relative intervention effect) for meta-analysis with the threshold of data associated with statistics. We planned to perform TSA on all outcomes included in the 'Summary of findings' table (Brok 2009; Pogue 1997; Wetterslev 2008).

The idea in TSA is that if the cumulative Z-curve crosses the boundary for benefit or harm before a diversity-adjusted required information size is reached, a sufficient level of evidence for the anticipated intervention effect has been reached with the assumed type I error and no further trials may be needed. If the cumulative Z-curve crosses the boundary for futility before a diversity-adjusted required information size is reached, the assumed intervention effect can be rejected with the assumed type II error and no further trials may be needed. If the Z-curve does not cross any boundary, then there is insufficient evidence to reach a conclusion. To construct the trial sequential monitoring boundaries, the required information size is needed and is calculated as the least number of participants needed in a well-powered single trial and subsequently adjusted for diversity among the included trials in the meta-analysis (Brok 2009; Wetterslev 2008). We applied TSA as it decreases the risk of type I and II errors due to sparse data and multiple updating in a cumulative meta-analysis, and it provides us with important information in order to estimate the risks of imprecision when the required information size is not reached. Additionally, TSA provides important information regarding the need for additional trials and the required information size of such trials (Wetterslev 2008).

We applied trial sequential monitoring boundaries according to an estimated clinically important effect. We based the required information size on an a priori effect corresponding to a 10% relative risk reduction (RRR) for beneficial effects of the interventions and a 30% relative risk increase for harmful effects of the interventions.

For continuous outcomes we performed TSA with MDs, by using the trials applying the same scale to calculate the required sample size. For continuous outcomes, we tested the evidence for the achieved differences in the cumulative meta-analyses.

For adjustment of heterogeneity of the required information size we used the diversity (D^2) estimated in the meta-analyses of included trials. When diversity was zero in a meta-analysis, we performed a sensitivity analysis using an assumed diversity of 20%.

Subgroup analysis and investigation of heterogeneity

We expected the following characteristics to introduce clinical heterogeneity and performed subgroup analyses to investigate interactions.

- Trials with a long duration (four years and longer) versus trials with a short duration (less than four years).
- Diagnostic 'prediabetes' criteria (IFG, IGT, HbA1c)
- Age, depending on data
- Sex
- Ethnicity, depending on data
- Comorbid conditions, such as hypertension or obesity
- Participants with previous gestational diabetes mellitus

Sensitivity analysis

We planned to perform sensitivity analyses to explore the influence of the following factors (when applicable) on effect sizes by restricting the analysis to the following.

- Published trials.
- Taking into account risk of bias, as specified in the 'Assessment of risk of bias in included studies' section.
- Trials using the following filters: imputation, language of publication, source of funding (industry versus other), or country.

We also planned to test the robustness of results by repeating the analysis using different measures of effect size (RR, OR, etc.) and different statistical models (fixed-effect and random-effects models).

Quality of evidence

We presented the overall quality of the evidence for each outcome according to the GRADE approach, which takes into account issues relating not only to internal validity (risk of bias, inconsistency, imprecision, publication bias) but also to external validity, such as directness of results. Two review authors (BH and BR) rated the quality of evidence for each outcome. We presented a summary of the evidence in 'Summary of findings' tables (Summary of findings for the main comparison; Summary of findings 2; Summary of findings 3). These tables provide key information about the best estimate of the magnitude of the effect of interventions, in relative terms and as absolute differences, the numbers of participants and trials addressing each important outcome, and rate the overall confidence in effect estimates for each outcome. We created the 'Summary of findings' tables on the basis of methods described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Schünemann 2011) by means of the table editor in Review Manager 5 (RevMan 2014), and included three appendices (Appendix 14; Appendix 15; Appendix 16) providing checklists as guides to the consistency and reproducibility of GRADE assessments (Meader 2014) to help with the standardisation of the 'Summary of findings' tables. Alternatively, we would have used the GRADEproGDT software (GRADEproGDT 2015) and would have presented evidence profile tables as an appendix. We presented results for the outcomes as described in the Types of outcome measures section. If meta-analysis was not possible, we

presented the results in a narrative format in the 'Summary of findings' tables. We justified all decisions to downgrade the quality of the evidence using footnotes, and we made comments to aid the reader's understanding of the review where necessary.

We presented a 'Summary of findings' table to report the following outcomes, listed according to priority.

- All-cause mortality
- Incidence of T2DM
- Serious adverse events
- Cardiovascular mortality
- Non-fatal myocardial infarction/stroke
- Health-related quality of life
- Socioeconomic effects

RESULTS

Description of studies

For a detailed description of studies, see the 'Characteristics of included studies', 'Characteristics of excluded studies', 'Characteristics of studies awaiting classification' and 'Characteristics of ongoing studies' sections.

Studies awaiting classification

We classified five trials in six references as studies awaiting classification (see 'Characteristics of studies awaiting classification' table).

Ongoing studies

We found three ongoing randomised controlled trials (RCTs) in nine references (NCT01530165; PREVIEW; PROPELS). We estimate the ongoing trials to include 23,808 participants. The definition of intermediate hyperglycaemia varied among the ongoing trials; one trial included participants with impaired glucose tolerance (IGT) (NCT01530165), one trial included participants with IGT, impaired fasting glucose (IFG) or both (PREVIEW), and one trial included participants with IFG or moderately elevated glycosylated haemoglobin A1c (HbA1c) (PROPELS). All the ongoing trials assessed one or more outcomes of interest for our review. Two of the ongoing trials' predefined outcomes stated that they would assess one of our primary outcomes (incidence of T2DM) (NCT01530165; PREVIEW). Future updates will include all ongoing trials, if possible.

Results of the search

The original Cochrane Review published in 2008 included eight RCTs. In this update we excluded two of these trials as they did not have intermediate hyperglycaemia as an inclusion criterion

(Bo 2007; Wing 1998). Thus, six trials of the original review remained (Da Qing 1997; DPP 2002; DPS 2001; IDPP 2006; Kosaka 2005; Oldroyd 2005). The updated search of the databases identified 2072 records after duplicates were removed (Figure 1). We excluded most of the references on the basis of their titles and abstracts because they clearly did not meet the inclusion criteria. We evaluated 181 references further. In this updated search we identified a total of 56 additional references for four of the already included trials of the 2008 review (Da Qing 1997; DPP 2002; DPS 2001; IDPP 2006). After screening the full-texts and evaluating the existing references from the 2008 review, 12 RCTs published in 127 records met our inclusion criteria. We excluded a total of 62 references from the updated search after full-text evaluation. Therefore, in addition to the six included trials of the Cochrane Review published in 2008 we included six more trials (EDIPS 2009; Hellgren 2016; HELP PD 2011; JDPP 2013; PODOSA 2014; SLIM 2003).

We continuously used a MEDLINE email alert service to identify newly published studies using the same search strategy as described for MEDLINE up to September 2017.

Included studies

A detailed description of the characteristics of included studies is presented elsewhere (see Characteristics of included studies; Table 1 and Appendix 2; Appendix 3; Appendix 4; Appendix 5; Appendix 6; Appendix 7; Appendix 8; Appendix 9; Appendix 10; Appendix 11; Appendix 12). The following is a succinct overview:

Source of data

We contacted all trial authors or investigators through email (see Appendix 13). When important information was lacking on ongoing studies and excluded studies, we contacted investigators for clarification.

Overview of trial populations

Ten trials reported the number of participants screened (Da Qing 1997; DPP 2002; EDIPS 2009; Hellgren 2016; HELP PD 2011; IDPP 2006; JDPP 2013; Oldroyd 2005; PODOSA 2014; SLIM 2003). Two trials did not report the number of participants randomised to each intervention group upon trial initiation (Da Qing 1997; Hellgren 2016). A total of 5238 participants were randomised; 11 trials evaluated diet plus physical activity (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Kosaka 2005; Oldroyd 2005; PODOSA 2014; SLIM 2003). The two trial randomising participants to physical activity only in one of their treatment arms did not report the number of participants randomised to the intervention groups (Da Qing 1997; Hellgren 2016); the same was the case for the one trial arm randomising to diet only (Da Qing 1997).

Ten trials provided information about sample size and power calculations (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Oldroyd 2005; PODOSA 2014; SLIM 2003).

The proportion of participants finishing the trial varied from 48% (SLIM 2003) to 98% (PODOSA 2014).

Trial design

Ten included trials were parallel RCTs and two trials had a cluster-randomised design (Da Qing 1997; PODOSA 2014). In Da Qing each clinic was randomised to carry out the intervention on each of the eligible participants attending the clinic (Da Qing 1997). A total of 33 health care clinics were included (Da Qing 1997). No intra-cluster correlation (ICC) coefficient was reported. However, we estimated it to be 0.05. The design effect was therefore estimated to be $1 + (\text{average cluster size} - 1) \times 0.05 = 1 + ((530/33) - 1) \times 0.05 = 1.75$. For dichotomous data, we divided both the number of participants experiencing an event as well as the number of participants by the design effect. For continuous data we only adjusted the sample size for the design effect. Means and standard deviations remained unchanged. In the PODOSA 2014 trial participants constituted 156 family clusters that were randomised (78 families with 85 participants were allocated to the intervention group and 78 families with 86 participants were allocated to the control group). First degree relatives living in the same city were not randomised separately. The ICC coefficient was assumed to be zero.

The number of participants varied from 78 (Oldroyd 2005) to 2161 (DPP 2002). One trial contributed 41% of the total number of all randomised participants (DPP 2002). Four trials were multi-centre trials (Da Qing 1997; DPP 2002; DPS 2001; JDPP 2013), four trials were single-centre trials (EDIPS 2009; Hellgren 2016; HELP PD 2011; Oldroyd 2005), and four trials did not provide any centre description (IDPP 2006; Kosaka 2005; PODOSA 2014; SLIM 2003). All trials were performed in outpatient settings.

None of the trials reported blinding of the participants and investigators. One trial had a run-in period of three weeks where participants had to fill out a diary and take placebo pills (DPP 2002). The duration of the intervention in the included trials varied from two to six years. Three trials had an extended follow-up period after the intervention period had stopped (Da Qing 1997; DPP 2002; DPS 2001). The extended follow-up period varied from 5 to 17 years. One trial based the sample size calculation on an anticipated incidence of T2DM during six years of follow-up. Trial authors said that they had planned six years' follow-up, but only reported three years of follow-up (JDPP 2013). Another trial originally planned a follow-up of three years, but was extended to six years in the course of the trial (SLIM 2003).

Six trials were performed in European countries (DPS 2001; EDIPS 2009; Hellgren 2016; Oldroyd 2005; PODOSA 2014;

SLIM 2003); two trials in the USA (DPP 2002; HELP PD 2011) and four trials in Asian countries (Da Qing 1997; IDPP 2006; JDPP 2013; Kosaka 2005).

Two trials included one or more intervention arms with metformin (DPP 2002; IDPP 2006). Results from these intervention arms will be reported elsewhere (Lü 2010). One of the trials originally included a troglitazone arm, which was discontinued due to liver toxicity of the drug (DPP 2002).

Three of the included trials stated that they had received grants from a pharmaceutical company (DPP 2002; DPS 2001; IDPP 2006). Eight trials reported non-commercial funding (Da Qing 1997; EDIPS 2009; Hellgren 2016; HELP PD 2011; JDPP 2013; Oldroyd 2005; PODOSA 2014; SLIM 2003). One trial did not report the funding source (Kosaka 2005).

Three trials were terminated early due to beneficial effects in the intervention group (DPP 2002; DPS 2001; IDPP 2006).

Participants

Four trials included only Asian people (Da Qing 1997; IDPP 2006; JDPP 2013; Kosaka 2005): two of these trials included Japanese people (JDPP 2013; Kosaka 2005), one trial included Asian Indians (IDPP 2006) and one trial included Chinese people (Da Qing 1997). One trial performed in the UK only included people of Indian or Pakistani origin (PODOSA 2014). Two trials included only white people (Oldroyd 2005; SLIM 2003). Two trials included people with different ethnicity (DPP 2002; HELP PD 2011): in one of the trials more than 50% of the included participants were white and about 20% African American (DPP 2002), the other trial reported about 75% were white and 25% African American (HELP PD 2011). Three trials did not report the ethnicity of the participants (DPS 2001; EDIPS 2009; Hellgren 2016): two of the trials might have included mainly white participants as they were conducted in Sweden and Finland (DPS 2001; Hellgren 2016).

All trial authors provided information on gender. One trial included only men (Kosaka 2005), the remaining trials included both men and women. All trials except one had a balanced distribution of women and men in the intervention and comparator groups, this trial included 54% women in the intervention group compared with 31% in the comparator group (Oldroyd 2005).

The age of the included participants varied from 45 to 63 years. All trials except one reported fasting glucose values at baseline (Hellgren 2016). Mean fasting glucose values at baseline varied from 5.5 mmol/L to 6.2 mmol/L. Nine trials reported two-hour glucose values after a glucose-load at baseline and ranged from 8.2 mmol/L to 9.2 mmol/L (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; IDPP 2006; JDPP 2013; Oldroyd 2005; PODOSA 2014; SLIM 2003). Glycosylated haemoglobin A1c (HbA1c) values were reported at baseline in six trials and ranged from 5.7% to 6.2% (DPP 2002; DPS 2001; IDPP 2006; JDPP 2013; Oldroyd 2005; SLIM 2003). One trial did not report any

glycaemic baseline values (Hellgren 2016).

All trials reported body mass index (BMI) at baseline. Three of the included trials required a minimum BMI for all eligible participants (DPP 2002; EDIPS 2009; HELP PD 2011). In two trials the mean BMI at baseline was less than 25 kg/m² (JDPP 2013; Kosaka 2005). Four trials had a mean BMI at baseline between 25 kg/m² to 30 kg/m² (Da Qing 1997; Hellgren 2016; IDPP 2006; SLIM 2003). Six trials reported a mean BMI at baseline above 30 kg/m² (DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; Oldroyd 2005; PODOSA 2014). None of the trials had a mean BMI at baseline above 35 kg/m². Most trials excluded participants with other endocrine conditions, hepatic or kidney disease.

Diagnosis of intermediate hyperglycaemia

The diagnosis applied in the included trials for identifying intermediate hyperglycaemia varied. Three trials applied the World Health Organization (WHO) 1985 diagnostic criteria for the definition of IGT (fasting plasma glucose (FPG) < 7.8 mmol/L and two-hour plasma glucose after oral glucose tolerance test (OGTT) between ≥ 7.8 mmol/L and < 11.1 mmol/L) (Da Qing 1997; DPS 2001; Oldroyd 2005). Three trials applied the WHO 1999 criteria for the definition of IGT (fasting plasma glucose (FPG) < 7.0 mmol/L and two-hour plasma glucose after OGTT between ≥ 7.8 mmol/L and < 11.1 mmol/L) (EDIPS 2009; IDPP 2006; JDPP 2013). For one of these trials it was stated that the diagnosis of IGT was based on the OGTT and trial authors did not clearly describe any measurement of FPG (EDIPS 2009). In the main publication it was described that intermediate hyperglycaemia was defined according to the WHO 1999 criteria, but the reference for the diagnostic criteria was the WHO 1985 reference (EDIPS 2009; WHO 1985). The investigators confirmed that the diagnosis of T2DM was established by FPG or two-hour plasma glucose (EDIPS 2009). Therefore, plasma glucose must have been measured (EDIPS 2009). One trial applied the WHO 1999 criteria for the definition of IFG (FPG ≥ 6.1 and < 7.8 mmol/L and two-hour glucose < 7.8 mmol/L) and/or IGT (FPG < 7.0 mmol/L and two-hour plasma glucose after OGTT between ≥ 7.8 mmol/L and < 11.1 mmol/L) (PODOSA 2014). One trial included people with IGT defined by FPG < 7.8 mmol/L and two-hour plasma glucose after 100 g OGTT between 8.9 mmol/L and 13.3 mmol/L, which roughly corresponds to 7.8 mmol/L to 11 mmol/L after a 75 g OGTT (Kosaka 2005). Therefore, the criterion was almost identical to the WHO 1980 criteria for IGT (FPG < 8.0 mmol/L and two-hour plasma glucose after OGTT between ≥ 8.0 mmol/L and < 11.0 mmol/L) (WHO 1980). One trial included people with fasting glucose levels between 5.3 mmol/L and 6.9 mmol/L (HELP PD 2011). This definition did not adhere to the definition by the WHO or American Diabetes Association (ADA), however, the definition was very close to the glycaemic levels recommended by ADA 2003 (FPG 5.6 mmol/L to 6.9 mmol/L) (ADA 2003). One trial applied the diagnostic criteria for impaired glucose de-

finied by ADA 1997 (FPG 5.3 mmol/L to 6.9 mmol/L and two-hour plasma glucose after OGTT between 7.8 and 11.0 mmol/L) (ADA 1997) (DPP 2002). For the Native American Indian clinics FPG less than 6.9 mmol/L with no lower limit applied. Before June 1997, the criterion for FPG was 5.6 to 7.7 mmol/L, or less than 7.7 mmol/L in the Native American Indian clinics (DPP 2002). A total of 54 participants (total in all three intervention groups) included in the Diabetes Prevention Program (DPP) had FPG above 7.0 mmol/L at baseline (DPP 2002). Thirteen percent of the participants included in the DPP had HbA1c ≥ 6.5% at baseline (DPP 2002). One trial defined IGT by FPG < 7.8 mmol/L and two-hour plasma glucose after OGTT between ≥ 7.8 mmol/L and < 12.5 mmol/L (SLIM 2003). No medical associations recommend these limits to diagnose IGT (SLIM 2003). Twenty-two participants of the initially randomised 147 participants had a two-hour glucose value above 11 mmol/L in this trial (SLIM 2003). One trial defined IFG as FPG > 6.0 mmol/L to < 7.0 mmol/L with two-hour plasma glucose after OGTT < 8.9 mmol/L, while IGT was defined as two-hour plasma glucose after OGTT between 8.8 mmol/L and < 12.2 mmol/L, and fasting glucose < 7.0 mmol/L (Hellgren 2016).

Interventions

All the participants in the included trials were treatment-naive with regard to pharmacological glucose-lowering interventions. Two of the included trials had more than one intervention group of relevance for this review (Da Qing 1997; Hellgren 2016). Hellgren 2016 initially analysed data from the two intervention groups separately. As the treatment effect was almost identical in both groups, they analysed the two groups together and thereafter designated them as the combined intervention group. Both the intervention arms in Hellgren 2016 had a more intense physical activity strategy than the comparator group. Diet advice was identical in both intervention groups and the comparator group. Da Qing 1997 had four intervention arms: physical activity only, diet only, physical activity plus diet and control group. We combined data for the physical activity only, diet only and physical activity plus diet group as one intervention group in the post-intervention follow-up period.

Ten trials aimed for weight reduction for all participants allocated to the intervention groups or only for participants with a BMI above a certain limit (this BMI limit varied among the included trials) (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; JDPP 2013; Kosaka 2005; Oldroyd 2005; PODOSA 2014; SLIM 2003). Participants with BMI above 25 kg/m² allocated to the diet-only group in Da Qing 1997 were encouraged to reduce their calorie intake, so they lost 0.5 kg to 1.0 kg per month until they achieved a BMI of 23 kg/m². For the other intervention groups in Da Qing 1997, the intervention intensity did not change according to BMI. Three trials aimed for a BMI less than 25 kg/m² in the diet plus physical activity group (DPS 2001; EDIPS

2009; Oldroyd 2005). One trial advised participants with a BMI above 22 kg/m² allocated to the diet plus physical activity group to lose weight (Kosaka 2005). One trial recommended a weight reduction of at least 7% in participants in the diet plus physical activity group (DPP 2002); two trials recommended a weight loss of 5% to 7% (HELP PD 2011; SLIM 2003); one trial aimed at 5% weight reduction in obese or overweight participants allocated to diet plus physical activity (JDPP 2013). One trial recommended a weight loss goal of 2.5 kg more in the diet plus physical activity group compared with the control group (PODOSA 2014).

The physical activity interventions differed largely among the trials. Some trials did not aim for a certain amount of minutes of activity, but just an increase in existing physical activity levels for the participants in the intervention group (Da Qing 1997; DPS 2001; Hellgren 2016). Other trials recommended physical activity of different intensity with a minimum number of minutes per day or week (DPP 2002; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Kosaka 2005; Oldroyd 2005; PODOSA 2014; SLIM 2003). Some defined physical activity levels in the intervention groups, which corresponded to the physical activity recommended in the control groups in other trials. Some trials promoted physical activity (Da Qing 1997; EDIPS 2009; HELP PD 2011; JDPP 2013; Kosaka 2005; Oldroyd 2005; PODOSA 2014) and others offered physical activity programmes (DPP 2002; DPS 2001; Hellgren 2016; SLIM 2003). Most programmes included walking and cycling.

Only one trial focused exclusively on physical activity interventions for the prevention of T2DM (Hellgren 2016).

The diet interventions were mainly based on caloric restriction, reduced fat intake and increased fibre intake (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Kosaka 2005; Oldroyd 2005; PODOSA 2014; SLIM 2003).

The number of contacts with the participants in the intervention groups ranged from 3 to 46 (Hellgren 2016; IDPP 2006). The intervention was applied to the participants in groups or on an individual basis. Nine of the trials applied both individual and group sessions for the participants in the intervention group (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; PODOSA 2014; SLIM 2003); three trials provided individual sessions only (Hellgren 2016; Kosaka 2005; Oldroyd 2005). In most of the trials the intervention facilitators were a physiotherapist, an exercise physiologist and a dietitian.

In one of the included trials, the control group did not receive any intervention (Oldroyd 2005). In the remaining included trials, the control group received recommendations, advice or education on how to increase physical activity and reduce calorie intake.

Three trials had an extended follow-up period after the intervention period had stopped (Da Qing 1997; DPP 2002; DPS 2001). In the Da Qing 1997 and DPS 2001 follow-up studies, the participants did not receive any kind of diet or physical activity advice

from the investigators. In the DPP 2002 follow-up study (Diabetes Prevention Program Outcome Study (DPPOS)) sessions on diet plus physical activity were offered to all participants every third month. The participants initially randomised to the DPP diet plus exercise group were also offered sessions in order to reinvigorate their self-management behaviours for weight loss (DPP 2002). In the Da Qing 1997 the participants were re-examined after 20 years and 23 years of follow-up. In the DPP 2002 and DPS 2001 follow-up studies the participants were examined yearly.

Outcomes

All included trials reported one or more of the primary outcomes for this review. All included trials, except one (Oldroyd 2005), explicitly specified the primary outcome. Nine trials predefined a primary outcome with interest for this review (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Kosaka 2005; SLIM 2003). Six trials had registered a protocol in a trials register (DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; JDPP 2013; PODOSA 2014). One trial changed its primary outcome from incidence of T2DM to weight change during the trial in order to ensure statistical power (PODOSA 2014). Weight change had originally been defined as a secondary outcome. Reporting on adverse events, macrovascular and microvascular complications was sparse.

Excluded studies

We excluded 41 trials after full-text evaluation (for details see Characteristics of excluded studies). We excluded 16 trials published in 26 references as the duration of the intervention was less than two years (D-CLIP; DH!AAN; Hesselink 2013; Huang 2007; J-DOIT; Kawahara 2008; Kinmonth 2008; Lindahl 1999; Marrero 2016; Page 1992; Ramachandran 2013; Sathish 2017; Savoye 2007; Thompson 2008; Villareal 2006; Yates 2011). We excluded 11 trials published in 12 references as they did not have intermediate hyperglycaemia as an inclusion criterion or the people with intermediate hyperglycaemia were analysed together with people of another glycaemic status, and separate data were not available (APHRODITE; Bo 2007; E-LITE; Eriksson 2006; NCT02374788; Rosas 2016; Schmidt 2016; SHINE; The Fasting Hyperglycaemia Study 1997a; Wing 1998; Yates 2012). We excluded three trials published in three references as they did not allocate the participants to diet, physical activity or both by randomisation (De la Rosa 2007; Eriksson 1991; Tao 2004). We excluded one trial due to inadequate description of the intervention group (Sartor 1980). We excluded 10 trials in 18 references as they did not compare the interventions of interest for this review (Grey 2004; Jarrett 1979; Let's Prevent; Liao 2002; Nanditha 2014; NCT02250066; PULSE; Saito 2011; Wein 1999; Wong 2013). Of these, seven trials in 14 references compared the same intensity of the diet plus physical activity intervention, but applied the

advice differently (e.g. one visit per year versus four visits per year) (Grey 2004; Let's Prevent; Nanditha 2014; PULSE; Saito 2011; Wein 1999; Wong 2013). We furthermore excluded 16 systematic reviews (Aguiar 2014; Gillett 2012; Gillies 2007; Glechner 2015; Gong 2015; Hopper 2011; ICER 2016; Norris 2005; Santaguida 2005; Selph 2015; Stevens 2015; Yamaoka 2005; Yates 2007; Yoon 2013; Yuen 2010; Zheng 2016).

Risk of bias in included studies

For details on the risk of bias of the included trials see [Characteristics of included studies](#).

For an overview of review authors' judgements about each risk of bias item for individual trials and across all trials see [Figure 2](#) and [Figure 3](#). No trial was free from risk of bias in all 'Risk of bias' domains.

Figure 2. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included studies (blank cells indicate that the particular outcome was not investigated in some studies).

Figure 3. Risk of bias summary: review authors' judgements about each risk of bias item for each included study (blank cells indicate that the study did not report that particular outcome).

Allocation

We judged eight of the trials to be at low risk of selection bias with regard to the method of randomisation and allocation concealment (DPP 2002; DPS 2001; EDIPS 2009; Hellgren 2016; HELP PD 2011; JDPP 2013; Oldroyd 2005; PODOSA 2014).

The remaining trials reported that the participants were randomised but provided no further description (Da Qing 1997; IDPP 2006; Kosaka 2005; SLIM 2003).

We evaluated trial baseline data for our predefined prognostic baseline variables. In one trial a significantly larger proportion of control participants reported engaging in regular physical activity at least once a week compared with intervention participants (53% versus 24%) and there were fewer women (10/32 (32%) than men (22/32 (69%)) in the control group compared with the

diet plus physical activity group (Oldroyd 2005). Another trial reported that physical activity was significantly higher at baseline in the diet plus physical activity group than in the control group (Da Qing 1997).

Blinding

Double-blinding was not possible or practical in the included trials due to the type of intervention.

One trial mentioned that an independent outcome committee evaluated the incidence of T2DM (DPS 2001). None of the remaining trials reported that a blinded outcome committee was instituted to assess outcomes during the intervention period.

Where measured, all primary outcomes of this review were investi-

gator assessed and we judged these to be at low risk of performance and detection bias. All the included trials reported blood glucose measurements performed by the investigators and we judged these outcomes measures to be at low risk of performance and detection bias. Two trials explicitly stated that glycaemic measures were masked for the investigators and participants until diabetes was confirmed (DPP 2002; DPS 2001). Non-serious adverse events and mild hypoglycaemia were partly or exclusively self-reported in all trials. Overall, we considered the risk of performance bias and detection bias to be low or unclear for our secondary outcomes.

Incomplete outcome data

We considered overall risk of attrition bias to be unclear for most of our outcomes. Ten trials reported the number of participants randomised and finishing the trial for each intervention group (DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Kosaka 2005; Oldroyd 2005; PODOSA 2014; SLIM 2003). Two trials did not describe how many participants were initially randomised to each intervention group but reported the number analysed (Da Qing 1997; Hellgren 2016). Three trials provided details on the participants not completing the trial (DPS 2001; JDPP 2013; PODOSA 2014).

Selective reporting

Six of the trials had a published protocol (DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; JDPP 2013; PODOSA 2014). We judged one trial as low risk of selective outcome reporting bias after the investigators provided additional information (Hellgren 2016). We judged eight of the included trials to be at high risk of reporting bias on one or more of the outcomes of relevance for our review (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Kosaka 2005). Three trials had an unclear risk of selective outcome reporting bias (Oldroyd 2005; PODOSA 2014; SLIM 2003). Two of the judgments of unclear risk of selective outcome reporting bias were based on lack of trial protocol (Oldroyd 2005; SLIM 2003) and one trial because the primary outcome was changed during the trial (PODOSA 2014). For more details see Appendix 6 and Appendix 7. One trial had a low risk of selective outcome reporting bias (Hellgren 2016).

Other potential sources of bias

We judged five trials to be at low risk of other bias (EDIPS 2009; Hellgren 2016; JDPP 2013; Oldroyd 2005; PODOSA 2014). Three trials had an unclear risk of other bias (HELP PD 2011; Kosaka 2005; SLIM 2003). We judged four trials to be at high risk of other bias, either because the trial was terminated early for benefit (DPP 2002; DPS 2001; IDPP 2006) or because trial authors did not report an ICC coefficient in their cluster-RCT making it necessary to estimate this coefficient (Da Qing 1997).

Four of the included trials had received grants from a pharmaceutical company and we judged these as unclear risk of other bias (DPP 2002; DPS 2001; HELP PD 2011; IDPP 2006). One trial did not report funding source (Kosaka 2005). It is known that receiving funding or provision of free drugs or devices from a pharmaceutical company leads to more favourable results and conclusions than sponsorship from other sources (Lundh 2017). One trial prolonged the intervention period without any explanation (SLIM 2003).

Effects of interventions

See: [Summary of findings for the main comparison Diet plus physical activity versus standard treatment](#); [Summary of findings 2 Diet versus physical activity or standard treatment](#); [Summary of findings 3 Physical activity versus standard treatment](#)

Baseline characteristics

For details of baseline characteristics, see [Appendix 3](#); [Appendix 4](#) and [Appendix 5](#).

Diet versus comparator

One trial compared diet with one or more comparators (Da Qing 1997). This trial had four intervention arms: diet only, physical activity only, diet plus physical activity and standard treatment (Da Qing 1997). The trial was cluster randomised. The trial had an extended follow-up period of 17 years. No ICC coefficient was reported. Based on an anticipated ICC coefficient of 0.05 we assumed a design effect of 1.75 (Higgins 2011). In the post-interventional follow-up period the trialists combined the three intervention groups into one composite intervention group. Data for the extended follow-up period for the combined intervention groups are described in the section 'Diet plus physical activity versus standard treatment'.

Diet versus physical activity

Only one trial compared diet with physical activity in one of its trial arms (Da Qing 1997). The overall quality of evidence was very low because of risk of reporting and other bias and serious imprecision (very sparse data)

Primary outcomes

All-cause mortality

Three out of 130 participants in the diet-only trial arm compared with none out of 141 participants in the physical activity-only trial arm died during the intervention period (when adjusting for cluster-RCT design: 2/74 versus 0/81). None of the participants

died due to cardiovascular disease. None of the participants who died had developed T2DM before death.

Incidence of T2DM

The incidence of T2DM was the primary outcome. T2DM was defined according to the WHO 1985 criteria (either a FPG \geq 140 mg/dL (7.8 mmol/L) or higher or a two-hour plasma glucose \geq 200 mg/dL (11.1 mmol/L) after 75 g OGTT) and confirmed with a repeated test 7 to 14 days after the first test or from a report of physician-diagnosed diabetes with evidence in the medical record of high glucose concentrations, or use of glucose-lowering drugs. Fifty-seven out of 130 participants in the diet-only group compared with 58 participants out of 141 in the physical activity only group developed T2DM during the intervention period (when adjusting for cluster-RCT design: 33/74 versus 33/81). The cumulative incidence of T2DM at six years was 43.8% (95% CI 35.3 to 52.3) in the diet only group compared with 41.1% (95% CI 33.4 to 49.4) in the physical activity only group (not adjusted for clustering). In the diet only group the incidence rate of T2DM was 10.0/100 person years (95% CI 7.5 to 12.5) compared with 8.3/100 person years (95% CI 6.4 to 10.3) in the physical activity only group (not adjusted for clustering). When analysing the incidence according to FPG 7.8 mmol/L or above, the rate was 3.7/100 person years (95% CI 2.1 to 5.3) in the diet only group compared with 5.3/100 person years (95% CI 3.6 to 7.0) in the physical activity only group (not adjusted for clustering).

Due to the differences in dietary advice according to BMI, [Da Qing 1997](#) evaluated separately the incidence of T2DM in those who had a BMI at baseline less than 25 kg/m² or 25 kg/m² or higher. Of the lean participants (BMI at baseline < 25 kg/m²), 21 (38.2%) out of 55 participants in the diet only compared with 15 (26.5%) out of 57 participants in the physical activity only group developed T2DM during the intervention period (when adjusting for clustering 12/31 versus 9/33). Of the overweight participants (BMI at baseline \geq 25 kg/m²), 36 (48%) out of 75 participants in the diet only compared with 43 (51.2%) out of 84 participants in the physical activity group developed T2DM during the intervention period (when adjusting for clustering 21/43 versus 26/46).

Of the 263 diabetes diagnoses made in all the intervention groups during the six years of intervention, 55 (21%) diagnoses were initially made by local physicians and confirmed by the city hospital with an OGTT; 208 (79%) were made as a result of the systematic OGTT during the trial.

Serious adverse events

No (serious) adverse events occurred in both groups.

Secondary outcomes

Cardiovascular mortality

None of the participants in either group died of cardiovascular reasons.

Non-fatal myocardial infarction

Not reported, however from a published abstract it was apparent that cardiovascular events were collected during the trial.

Non-fatal stroke

Not reported, however from a published abstract it was apparent that cardiovascular events were collected during the trial.

Amputation of lower extremity

Not reported.

Blindness or severe vision loss

[Da Qing 1997](#) reported the incidence of severe retinopathy among the participants originally assigned to diet only (4.5/1000 person years (95% CI 1.8 to 7.1)) compared with physical activity only (5.3/1000 person years (95% CI 2.5 to 8.0)) after 20 years of follow-up (i.e. 14 years after the end of intervention). This difference was not statistically significant.

End-stage renal disease

Not reported.

Non-serious adverse events

No adverse events occurred in either group.

Hypoglycaemia

Not reported.

Health-related quality of life

Not reported.

Time to progression to T2DM

Not reported.

Measures of blood glucose control

Fasting glucose

At the end of follow-up after six years of intervention, FPG in the diet only group was 7.0 mmol/L (SD 4.4) based on 130 participants (74 participants when adjusting for clustering) compared with 6.8 mmol/L (SD 2.2) in 141 participants (81 participants when adjusting for clustering) in the physical activity group.

Glucose two hours after an oral glucose load

At the end of follow-up after six years of intervention, two-hour glucose after an oral glucose load in the diet only group was 10.5 mmol/L (SD 4.9) based on 130 participants (74 participants when adjusting for clustering) compared with 10.5 mmol/L (SD 3.9) in 141 participants (81 participants when adjusting for clustering) in the physical activity group.

HbA1c

Not reported.

Socioeconomic effects

Not reported.

Diet versus standard treatment

Only one trial compared diet with standard treatment in one of its trial arms (Da Qing 1997). The overall quality of evidence was very low because of risk of reporting and other bias and serious imprecision (very sparse data)

Primary outcomes

All-cause mortality

Three out of 130 participants in the diet only group compared with three participants out of 133 in the standard treatment group died during the intervention period (when adjusting for cluster-design: 2/74 versus 2/76). None of the participants died because of cardiovascular disease. None of the participants who died had developed T2DM before death. The HR (adjusted for age and clustering) when combining diet only, physical activity only and diet plus physical activity compared with standard treatment was 1.33 (95% CI 0.45 to 3.92) at the end of the intervention period.

Incidence of T2DM

Fifty-seven out of 130 participants in the diet only group compared with 90 participants out of 133 in the standard treatment group developed T2DM during the intervention period (when adjusting for cluster design: 33/74 versus 51/76).

The cumulative incidence of T2DM at six years was 43.8% (95% CI 35.3 to 52.3) in the diet only group compared with 67.7% (95% CI 59.8 to 75.2) in the standard treatment group (not adjusted for clustering). In the diet only group, the incidence rate of T2DM (defined according to WHO 1985) was 10.0/100 person years (95% CI 7.5 to 12.5) compared with 15.7/100 person years (95% CI 12.7 to 18.7) in the standard treatment group (not adjusted for clustering). When analysing the incidence according to FPG 7.8 mmol/L or higher, the rate was 3.7/100 person years (95% CI 2.1 to 5.3) in the diet only group compared with 9.6/100 person years (95% CI 7.2 to 12.0) in the standard treatment group (not adjusted for clustering).

Due to the differences in dietary advice according to BMI, the trialists evaluated separately incidence of T2DM in those who had BMI at baseline less than 25 kg/m² or 25 kg/m² or higher. Of the lean participants (BMI at baseline < 25 kg/m²) 21 (38.2%) out of 55 participants in the diet only group compared with 30 (60%) out of 50 participants in the standard treatment group developed T2DM during the intervention period (when adjusting for clustering 12/31 versus 17/29). Of the obese participants (BMI at baseline ≥ 25 kg/m²) 36 (48%) out of 75 participants in the diet only group compared with 60 (72.3%) out of 83 participants in the standard treatment group developed T2DM during the intervention period (when adjusting for clustering 21/43 versus 34/47).

After 20 years of follow-up (i.e. 14 years after the intervention had stopped) the HR (adjusted for age and clustering) for the diet only group versus standard treatment group was 0.58 (95% CI 0.38 to 0.89).

Serious adverse events

No (serious) adverse events occurred in either group.

Secondary outcomes

Cardiovascular mortality

None of the participants in either group died of cardiovascular reasons.

Non-fatal myocardial infarction

Not reported, however from a published abstract it was apparent that cardiovascular events were collected during the trial.

Non-fatal stroke

Not reported, however from a published abstract it was apparent that cardiovascular events were collected during the trial.

Amputation of lower extremity

Not reported.

Blindness or severe vision loss

Not reported.

End-stage renal disease

Not reported.

Non-serious adverse events

No adverse events occurred in either group.

Hypoglycaemia

Not reported.

Health-related quality of life

Not reported.

Time to progression to T2DM

Not reported.

Measures of blood glucose control***Fasting glucose***

FPG at the end of follow-up after six years of intervention in the diet only group was 7.0 mmol/L (SD 4.4) based on 130 participants (74 participants when adjusting for clustering) compared with 7.6 mmol/L (SD 2.6) in 133 participants (76 participants when adjusting for clustering) in the standard treatment group.

Glucose two hours after an oral glucose load

Glucose two hours after an oral glucose load at the end of follow-up after six years of intervention in the diet only group was 10.5 mmol/L (SD 4.9) based on 130 participants (74 participants when adjusting for clustering) compared with 12.4 mmol/L (SD 4.2) in 133 participants (76 participants when adjusting for clustering) in the standard treatment group.

HbA1c

Not reported.

Socioeconomic effects

Not reported.

Physical activity versus standard treatment

Two trials compared physical activity with one or more controls (Da Qing 1997; Hellgren 2016). Da Qing 1997 had four intervention arms: diet only, physical activity only, diet plus physical activity and standard treatment (Da Qing 1997). The trial was cluster randomised. No ICC coefficient was reported. Based on an anticipated ICC coefficient of 0.05 we assumed a design effect of 1.75 (Higgins 2011). In the post-interventional follow-up period, Da Qing 1997 combined the three intervention groups into one composite intervention group. Data for the extended follow-up period for the combined intervention group are described in the section 'Diet plus physical activity versus standard treatment'.

One trial had two physical activity groups (Hellgren 2016), and initially analysed data from these two groups separately (Hellgren 2016). As the outcomes proved to be essentially the same in both groups, they analysed the physical activity groups together and thereafter designated them as the combined physical activity group. Both intervention arms in Hellgren 2016 had a more intense physical activity strategy than the comparator group. The diet advice was identical in the physical activity groups and the standard treatment group.

The two trials comparing physical activity with standard treatment varied according to several important prognostic baseline characteristics (e.g. Da Qing 1997 included only Asian Chinese and the average age of the participants was about 45 years compared with Hellgren 2016 including presumably only white people with an average age of participants of 63 years). Da Qing 1997 included people with IGT according to the WHO 1985 criteria. Hellgren 2016 included participants with IGT, IFG or both. Da Qing 1997 had a duration of the intervention of six years compared with three years in Hellgren 2016.

The overall quality of evidence was very low mainly because of risk of bias and imprecision (sparse data)

Primary outcomes**All-cause mortality**

One trial reported that none of the 141 participants in the physical activity only group compared with three participants out of 133 in the standard treatment group died during the intervention period (when adjusting for cluster-RCT design: 0/81 versus 2/76) (Da Qing 1997). None of the participants who died had developed

T2DM before death. The HR (adjusted for age and clustering) when combining diet only, physical activity only and diet plus physical activity compared with standard treatment was 1.33 (95% CI 0.45 to 3.92) at the end of the intervention period (Da Qing 1997). The other trial reported that four participants died; three out of 84 in the physical activity group and one out of 39 in the standard treatment group. It was not possible to judge to which group the deceased participants had originally been randomised, however, the investigators provided this additional information (Hellgren 2016) (Analysis 1.1).

Incidence of type 2 diabetes

Da Qing 1997's primary outcome was the incidence of T2DM, which they defined according to the WHO 1985 criteria (either a FPG \geq 7.8 mmol/L or higher or a two-hour plasma glucose \geq 11.1 mmol/L after a 75 gram OGTT) and confirmed with a repeat test 7 to 14 days after the first test or from a report of physician-diagnosed diabetes with evidence in the medical record of high glucose concentrations, or use of glucose-lowering drugs. Fifty-eight out of 141 participants in the physical activity only group compared with 90 participants out of 133 in the standard treatment group developed T2DM during the intervention period (when adjusting for cluster design: 33/84 versus 51/76) - Analysis 1.2.

The cumulative incidence of T2DM at six years was 41.1% (95% CI 33.4 to 49.4) in the physical activity only group compared with 67.7% (95% CI 59.8 to 75.2) in the standard treatment group (not adjusted for clustering). In the physical activity only group the incidence of T2DM (defined according to WHO 1985) was 8.3/100 person years (95% CI 6.4 to 10.3) compared with 15.7/100 person years (95% CI 12.7 to 18.7) in the standard treatment group (not adjusted for clustering). When analysing the incidence according to FPG 7.8 mmol/L or higher, the incidence of T2DM was 5.3/100 person years (95% CI 3.6 to 7.0) in the physical activity only group compared with 9.6/100 person years (95% CI 7.2 to 12.0) in the standard treatment group (not adjusted for clustering) (Da Qing 1997).

Of the lean participants (BMI at baseline $<$ 25 kg/m²), 15 (26.3%) out of 57 participants in the physical activity only group compared with 30 (60%) out of 50 in the standard treatment group developed T2DM during the intervention period (when adjusting for clustering 9/33 versus 17/29). Of the overweight participants (BMI at baseline \geq 25 kg/m²), 43 (51.2%) out of 84 participants in the physical activity only group compared with 60 (72.3%) out of 83 participants in the standard treatment group developed T2DM during the intervention period (when adjusting for clustering 25/48 versus 34/47) (Da Qing 1997).

For all the 263 diabetes diagnoses made in all the intervention groups during the six years of intervention in Da Qing 1997, 55 diagnoses (21%) were initially made by local physicians and confirmed by the city hospital with an OGTT; 208 (79%) were

made as a result of the systematic OGTT during the trial.

The other trial reporting T2DM defined the condition by FPG more than 6.9 mmol/L and/or two-hour plasma glucose concentration more than 12.1 mmol/L (Hellgren 2016). Ten (11.9%) out of 84 participants in the physical activity group compared with seven (17.9%) out of 39 participants in the standard treatment group developed T2DM during the intervention period (Analysis 1.2).

In the physical activity group 32 participants had IGT only; 38 had IFG only and 11 had IGT and IFG combined. Of the 32 participants with IGT at baseline in the physical activity group, seven (22%) developed T2DM; of the 38 with IFG at baseline, three (7.8%) developed T2DM; of the 11 with combined IFG and IGT, two (18.2%) developed T2DM. In the standard treatment group 15 participants had IGT only; 21 had IFG only and six had IGT and IFG combined. Of the 15 participants with IGT at baseline in the standard treatment group five (33%) developed T2DM; of the 21 with IFG at baseline, two (7.8%) developed T2DM; of the six with combined IFG and IGT, four (66.7%) developed T2DM (Hellgren 2016). The number of the participants included in the subgroups of different glycaemic definitions of intermediate hyperglycaemia did not add up to the total number of participants developing T2DM provided by the investigators of the trial (physical activity 81 versus 84 and standard treatment 32 versus 39) (Hellgren 2016). We contacted the investigators about the participants who did not participate in the final follow-up and asked if these people had developed T2DM (Hellgren 2016).

One trial had an extended follow-up period (Da Qing 1997). The HR for the incidence of T2DM (adjusted for age and clustering) of physical activity versus standard treatment after 20 years of follow-up was 0.51 (95% CI 0.31 to 0.83) (Da Qing 1997).

Serious adverse events

One trial reported that they did not observe any adverse events. However, this seems unlikely, because the publications indicated that serious adverse events were experienced (e.g. cardiovascular events) (Da Qing 1997). The other trial did not publish any data on serious adverse events, but these were provided by the investigators (Hellgren 2016). No further definition of the outcome was provided. Three (4.5%) out of 66 participants in the physical activity group versus one (2.6%) out of 39 participants in the standard treatment group experienced a serious adverse event (Hellgren 2016) (Analysis 1.3).

Secondary outcomes

Cardiovascular mortality

None of the participants in the groups died of cardiovascular reasons.

Non-fatal myocardial infarction

One trial reported that none of the 66 participants in the physical activity group compared with three (9.7%) of 31 participants in the standard treatment group experienced a non-fatal myocardial infarction. No further definition of the outcome was provided. These data were provided by the investigators (Hellgren 2016).

Non-fatal stroke

One trial reported that one (1.5%) out of 66 participants in the physical activity group compared with one (3.2%) out of 31 participants in the standard treatment group experienced a non-fatal stroke. No further definition of the outcome was provided. These data were provided by the investigators (Hellgren 2016).

Amputation of lower extremity

One trial reported that none of the participants in the trial experienced an amputation of the lower extremity. No further definition of the outcome was provided. These data were provided by the investigators (Hellgren 2016).

Blindness or severe vision loss

Not reported.

End-stage renal disease

Not reported.

Non-serious adverse events

One trial reported that no adverse event was observed (Da Qing 1997).

Hypoglycaemia

One trial reported that none of the participants in the trial experienced hypoglycaemia. No further definition of the outcome was provided. These data were provided by the investigators (Hellgren 2016).

Health-related quality of life

One of the trials comparing physical activity with standard treatment reported health-related quality of life (HrQoL) (Hellgren 2016). Information on this outcome was provided by the investigators. It is unclear whether they assessed HrQoL with a validated instrument. It was measured by two questions, where participants graded their total physical and mental health from 1 to 7. Participants also graded their general health from 1 (best) to 5 (very bad). There were questions about sleep and energy. The investigators reported that 13 participants (27%) in the physical activity group

reported that HrQoL from baseline to end of follow-up worsened, in 21 participants (43%) it was unchanged and in 14 participants (29%) it increased - the total number of participants in the physical activity group included in the analyses was 48 participants. The investigators reported that eight participants (35%) in the standard treatment group rated themselves worsened, 10 participants (43%) remained unchanged and five participants (22%) improved - the total number of participants in the standard treatment group included in the analyses was 23 (Hellgren 2016). These data were provided by the investigators.

Time to progression to type 2 diabetes

Not reported.

Measures of blood glucose control

Fasting glucose

FPG after six years of intervention in the physical activity group was 6.8 mmol/L (SD 2.2) based on 141 participants (81 participants when adjusting for clustering) compared with 7.6 mmol/L (SD 2.6) in 133 participants (76 participants when adjusting for clustering) in the standard treatment group (Da Qing 1997). The investigators of Hellgren 2016 provided data on change in fasting plasma glucose on request (Analysis 1.4).

Glucose two hours after an oral glucose load

One trial reported glycaemic values after six years of intervention. The two-hour glucose after an oral glucose load in the physical activity group was 10.5 mmol/L (SD 3.9) based on 141 participants (81 participants when adjusting for clustering) compared with 12.4 mmol/L (SD 4.2) in 133 participants (76 participants when adjusting for clustering) in the standard treatment group (Da Qing 1997). The investigators of Hellgren 2016 provided data on change in glucose two hours after an OGTT on request (Analysis 1.5).

HbA1c

Not reported.

Socioeconomic effects

Not reported.

Diet plus physical activity versus standard treatment

Eleven trials compared the combination of diet plus physical activity with standard treatment or no intervention (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Kosaka 2005; Oldroyd 2005; PODOSA 2014; SLIM 2003). Da Qing 1997 had four intervention arms: diet only, physical activity only, diet plus physical activity and standard treatment. The trial was cluster randomised. The authors reported that HRs at 20 and 23 years of follow-up were adjusted for clustering, but no information of adjustment for clustering was provided at the end of intervention. No ICC coefficient was reported (Da Qing 1997). Based on an anticipated ICC coefficient of 0.05 we assumed a design effect of 1.75 (Higgins 2011). In the post-intervention follow-up period Da Qing 1997 combined the three intervention groups (diet only, physical activity only, diet plus physical activity) into one intervention group. Two other trials also reported data with relevance to this review after the intervention had been stopped (DPP 2002; DPS 2001).

Da Qing 1997 included people with IGT according to the WHO 1985 criteria (two-hour plasma glucose ≥ 6.7 mmol/L and < 11.0 mmol/L after an OGTT).

Nine trials exclusively included people with IGT (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; IDPP 2006; JDPP 2013; Kosaka 2005; Oldroyd 2005; SLIM 2003). One trial included people with IGT, IFG or both (PODOSA 2014). One trial included people with FPG levels between 5.3 to 6.9 mmol/L (HELP PD 2011).

Primary outcomes

All-cause mortality

Ten trials reported data on all-cause mortality (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Oldroyd 2005; PODOSA 2014; SLIM 2003). None of these trials had predefined all-cause mortality as a primary outcome (see Appendix 6). In Da Qing 1997 five out of 126 participants died in the diet plus physical activity group versus three out of 133 participants in the standard treatment group (when adjusted for clustering; diet plus physical activity three out of 72 participants versus standard treatment two out of 76 participants). Most of the trials reporting death were from trials with low risk of selection bias (DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; JDPP 2013; Oldroyd 2005; PODOSA 2014).

A total of 12 deaths were reported in 2049 participants in the diet plus physical activity group versus 10 out of 2050 participants in the comparator group (RR 1.12, 95% CI 0.50 to 2.50; $P = 0.86$; 4099 participants, 10 trials; very low-quality evidence). Funnel plot asymmetry was not present. The 95% prediction interval ranged from 0.44 to 2.88 (Analysis 2.1).

Trial sequential analysis (TSA) showed that 0.61% of the diversity-adjusted information size was accrued so far to detect or reject

a 10% relative risk reduction (RRR). Diversity was zero, but we applied a diversity of 20% when calculating the diversity-required information size, as heterogeneity is likely to increase when future trials are included. As only a minor fraction of the diversity-adjusted required information size to detect or reject a 10% RRR was accrued, we could not calculate the TSA-adjusted 95% CIs with diversity at 20%. If a diversity of 0% was applied, then 0.77% of the diversity-adjusted information size was accrued to detect or reject a 10% RRR. Still, we could not calculate the TSA-adjusted 95% CIs.

Subgroup analyses according to the duration of the intervention (≥ 4 years) versus trials with short duration (< 4 years), diagnostic criteria (IGT versus other); age (≥ 50 years versus < 50 years); ethnicity (Asian only versus other and mixed ethnicities); morbidity (BMI ≥ 30 kg/m² versus < 30 kg/m²) showed no statistically significant interactions (Appendix 18). We could not perform subgroup analyses according to sex and previous gestational diabetes due to lack of data.

Sensitivity analyses including only trials with low risk of selection bias (DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; JDPP 2013; Oldroyd 2005; PODOSA 2014) did not substantially change the effect estimate (RR 1.14, 95% CI 0.42 to 3.12; $P = 0.79$).

One trial reported a HR (adjusted for age and clustering) when combining diet only, physical activity only and diet plus physical activity compared with control at the end of intervention (HR 1.33, 95% CI 0.45 to 3.92) (Da Qing 1997).

Three trials comparing diet plus physical activity had extended follow-up periods (Da Qing 1997; DPP 2002; DPS 2001). Two of these reported mortality data during the follow-up period (Da Qing 1997; DPS 2001).

One trial reported that six out of 257 participants originally randomised to diet plus physical activity group died compared with 10 out of 248 participants in the control arm after a median follow-up of 10.6 years (i.e. 6.6 years after the intervention had stopped) (DPS 2001). Mortality in the former diet plus physical activity group was 2.2/1000 person years (95% CI 1.0 to 0.35) compared with 3.8/1000 person years (95% CI 2.0 to 7.0) in the former control group. The HR was 0.57 (95% CI 0.21 to 1.58) (unknown adjusting) (DPS 2001).

One trial reported a HR (adjusted for age and clustering) when combining diet only, physical activity only and diet plus physical activity compared with control to be 0.96 (95% CI 0.65 to 1.41) after 20 years of follow-up (i.e. 14 years after the intervention had stopped) (Da Qing 1997). The same trial reported 23 years of follow-up (i.e. 17 years after the intervention had stopped); 121 out of 430 participants (after cluster-adjustment: 69/246) allocated to the former intervention group (combined diet only, physical activity only and diet plus physical activity) versus 53 out of 138 (after cluster-adjustment 30/79) in the former control group died (Da Qing 1997). The cumulative incidence of all-cause mortality was 28.1% (95% CI 23.9 to 32.4) in the combined

former intervention group and 38.4% (95% CI 30.3 to 46.5) in the former comparator group, with a HR (adjusted for cluster-randomisation) of 0.71 (95% CI 0.51 to 0.99; $P = 0.049$). Deaths per 1000 person years were 14.3 (95% CI 11.8 to 16.9) in the combined former intervention group compared with 19.9 (95% CI 14.5 to 25.2) in the former comparator group.

Post-hoc subgroup analyses after 23 years of follow-up showed that, among women, the cumulative incidence of all-cause mortality in the former comparator group was elevated compared with the combined former intervention group (HR 0.46, 95% CI 0.24 to 0.87; $P = 0.02$). The number of deaths included in this post-hoc analysis was 30 deaths in 200 women in the combined former intervention group compared with 17 deaths out of 59 women in the former comparator group (Da Qing 1997). For men the intervention did not show statistically significant differences (91 deaths among 230 male participants in the combined former intervention group compared with 36 deaths out of 79 participants in the former comparator group; HR 0.97 (95% CI 0.97 to 1.46). We performed multivariable analyses in order to test if different baseline characteristics could explain the differences (e.g. smoking, age), but the difference between men and women persisted. However, when the time to onset of T2DM was included in the multivariable models, then the intervention variable was no longer significant (Da Qing 1997).

Incidence of type 2 diabetes

Eleven trials reported data on the incidence of T2DM. The definition of T2DM varied among the included trials. Three trials applied the WHO 1985 diagnostic criteria (either FPG ≥ 7.8 mmol/L or higher or a two-hour plasma glucose ≥ 11.1 mmol/L after a 75 g OGTT) (Da Qing 1997; DPS 2001; Oldroyd 2005); four trials applied the WHO 1999 criteria to establish the diagnosis of T2DM (either FPG ≥ 7.0 mmol/L and/or a two-hour plasma glucose concentration ≥ 11.1 mmol/L after a 75 g OGTT) (EDIPS 2009; IDPP 2006; JDPP 2013; SLIM 2003). One trial established the diagnosis of T2DM based on the ADA 1997 diagnostic criteria (FPG ≥ 7.0 mmol/L or a two-hour plasma glucose ≥ 11.1 mmol/L after a 75 g OGTT (i.e. identical to WHO 1999 criteria)) (DPP 2002). One trial applied FPG levels above 7.0 mmol/L to establish the diagnosis of T2DM (HELP PD 2011). One trial applied FPG levels above 7.8 mmol/L to establish the diagnosis of T2DM (Kosaka 2005). One trial established the diagnosis of T2DM based on two-hour plasma glucose of 11.1 mmol/L or higher after a 75 g OGTT (PODOSA 2014). Furthermore, four trials also defined the diagnosis of T2DM as reported by a physician or the use of glucose-lowering drugs (Da Qing 1997; EDIPS 2009; HELP PD 2011; PODOSA 2014).

A total of 315 out of 2122 participants developed T2DM in the diet plus physical activity group versus 614 out of 2389 participants in the comparator group (RR 0.57, 95% CI 0.50 to 0.64; $P < 0.00001$; 4511 participants, 11 trials; moderate quality evi-

dence). The 95% prediction interval ranged from 0.50 to 0.65. TSA showed firm evidence for a 10% RRR in favour of diet plus physical activity. Funnel plot asymmetry was not present (Analysis 2.8).

Of the 12 participants in PODOSA 2014 diagnosed with T2DM in the diet plus physical activity group, only two participants were diagnosed with OGTT at the third year of the trial. The remaining 10 participants who developed T2DM in the diet plus physical activity group during the trial were diagnosed by a physician. In the control group 10 participants were diagnosed with T2DM, based on a physicians' diagnosis and seven participants were diagnosed with the OGTT at the third year of the trial (PODOSA 2014). The incidence rate of T2DM in the Japan Diabetes Prevention Program (JDPP 2013) trial was 2.7/100 person years in the diet plus physical activity group compared with 5.1/100 person years in the control group. The JDPP trial included both lean and obese participants with a BMI ranging from 16.8 to 39.6 kg/m². Additional analyses were made according to BMI at baseline. T2DM developed in five out of 52 participants in the lowest quartile (two from the control group and three from the intervention group) during the three years. An effect of the behaviour-changing intervention was therefore not apparent in this lowest BMI quartile. However, the cut-off point for the lower quartile was not available from the publication (JDPP 2013). Subgroup analysis for the participants with BMI more than 22.5 kg/m² revealed a significant decrease in the cumulative incidence of T2DM with the intervention ($P = 0.027$). The cumulative incidence of T2DM was significantly lower in the diet plus physical activity group compared with controls among participants with baseline HbA1c levels of 5.7% or higher, while this was not found among participants with baseline HbA1c levels less than 5.7% (JDPP 2013).

The Indian Diabetes Prevention Programmes (IDPP 2006) trial reported a cumulative incidence of T2DM at 39.3% (95% CI 30.4 to 48.5) in the diet plus physical activity group compared with 55.0% (95% CI 46 to 63.5) in the control group (IDPP 2006). The number of participants needed to be treated to prevent one T2DM case was 6.4. The HR for developing T2DM (adjusted for sex, age, family history of diabetes, BMI, waist circumference, baseline fasting and two-hour glucose and corresponding insulin values, hypertension and smoking) for the diet plus physical activity group compared with the control group was 0.62 (95% CI 0.23 to 1.02; $P = 0.018$) (IDPP 2006). Plasma glucose two-hour after an OGTT, fasting and two-hour insulin showed independent influence on the development of T2DM (IDPP 2006).

In Da Qing 1997 the incidence rate of T2DM in the diet plus physical activity group was 9.6/100 person years (95% CI 7.2 to 12.0) compared with 15.7/100 person years (95% CI 12.7 to 18.7) in the control group (not adjusted for clustering). When analysing the incidence rate of T2DM according to fasting plasma glucose of 7.8 mmol/L or higher, the incidence rate of T2DM was 5.5/100 person years (95% CI 3.7 to 7.3) in the diet plus physical activity group compared with 9.6/100 person years (95%

CI 7.2 to 12.0) in the control group (not adjusted for clustering) (Da Qing 1997). The HR (adjusted for age and clustering) when combining diet only, physical activity only and diet plus physical activity compared with control was 0.49 (95% CI 0.33 to 0.73). Of the lean participants (BMI at baseline < 25 kg/m²), 16 (34.8%) out of 46 participants in the diet plus physical activity group compared with 30 (60%) out of 50 in the control group developed T2DM during the intervention period (when adjusting for clustering 9/26 versus 17/29). Of the obese participants (BMI at baseline ≥ 25 kg/m²), 42 (52.5%) out of 80 participants in the diet plus physical activity group compared with 60 (72.3%) out of 83 in the control group developed T2DM during the intervention period (when adjusting for clustering 24/46 versus 34/47) (Da Qing 1997).

A total of 263 participants were diagnosed with T2DM during the six years of intervention; 55 diagnoses (21%) were initially made by local physicians and confirmed by the city hospital with an OGTT; 208 (79%) were made as a result of the systematic OGTTs during the trial (Da Qing 1997).

In DPS 2001 the incidence rate of T2DM after a median of four years' intervention was 4.2/100 person years in the diet plus physical activity group compared with 7.4/100 person years in the control group. The HR (adjusted for sex, age, BMI, waist circumference, fasting and two-hour glucose, insulin, homeostatic model assessment - insulin resistance (HOMA-IR), estimated risk with The Finnish Diabetes Risk Score (FINDRISC)) was 0.54 (95% CI 0.37 to 0.78) in favour of the diet plus physical activity group. Incidence and HRs were present for several baseline variables (sex, age, BMI, waist circumference; fasting plasma glucose; two-hour glucose; fasting insulin; HOMA-IR and FINDRISC) (Appendix 19). The interaction between age at baseline as a continuous variable and intervention effect was statistically significant (P = 0.0130) (Appendix 19). Baseline glycaemic (fasting and two-hour glucose) status was directly associated with diabetes incidence in the diet plus physical activity group and the control group. However, the effect of intervention was independent of glycaemic status (Appendix 19).

The trial authors performed several subgroup analyses according to different prognostic baseline variables in DPP 2002 (Appendix 19). Subgroup analyses found that treatment effects did not differ substantially according to sex, race or ethnic group; however, the effect of the behaviour-changing intervention was greater among participants with lower baseline glucose concentrations two hours after a glucose load.

One publication presented a composite analysis including three of the included trials (DPS 2001; EDIPS 2009; SLIM 2003). A total of 749 participants were included in the analyses with a mean follow-up of 3.1 years (Penn 2013). The HR for the incidence of T2DM was 0.42, (95% CI 0.29 to 0.60; P < 0.001) in favour of diet plus physical activity. On average 7.4 people had to undergo diet plus physical activity for a mean of 3.1 years to prevent one case of T2DM (number needed to treat for an additional beneficial

outcome 22.9 for one year).

Subgroup analysis: analysing trials according to the duration of the intervention and diagnostic criteria showed no interaction between the subgroups (P = 0.88 and P = 0.42) (Analysis 2.9; Analysis 2.10) (Appendix 18). Subgroup analyses stratifying the included trials according to age, ethnicity and obesity showed statistically significant interactions (Appendix 18) (Analysis 2.11; Analysis 2.12; Analysis 2.13). However, the CIs in these analyses overlap to a small degree. As a caveat, these observations should be regarded as hypothesis-generating only. We could not perform subgroup analyses according to sex and previous gestational diabetes due to lack of data.

Sensitivity analysis: we could not perform sensitivity analysis according to publication status (all included trials were published) and language of publication (all included trials were published in English). Sensitivity analysis restricted to only trials with low risk of selection bias showed a RR of 0.50 (95% CI 0.44 to 0.58; P < 0.00001) (DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; JDPP 2013; Oldroyd 2005; PODOSA 2014), that is, it did not show substantial differences to including all trials. Analysing trials performed in Asia showed a RR of 0.67 (95% CI 0.56 to 0.82; P < 0.0001) (Da Qing 1997; IDPP 2006; JDPP 2013; Kosaka 2005); for trials performed in Europe, the RR was 0.54 (95% CI 0.41 to 0.72; P < 0.0001) (DPS 2001; EDIPS 2009; Oldroyd 2005; PODOSA 2014; SLIM 2003).

Three trials reported the incidence of T2DM after an extended follow-up period (Da Qing 1997; DPP 2002; DPS 2001). One trial reported the incidence of T2DM after nine years (i.e. five years after the end of the intervention period). A total of 106 in the diet plus physical activity group out of 265 participants versus 140 out of 257 participants in the control group were diagnosed with T2DM (DPS 2001). The incidence of T2DM per 100 person years was 4.5 (95% CI 3.8 to 5.5) in the diet plus physical activity group versus 7.2 (95% CI 6.1 to 8.5) in the control group; the HR (adjusted for sex, age, BMI and two-hour glucose) was 0.61 (95% CI 0.48 to 0.79; P < 0.001) and the absolute risk reduction was 19%. The number needed to treat to prevent one case of T2DM was 5.2. In the post-intervention follow-up (median seven years), 62 out of 200 participants in the former diet plus physical activity group, compared with 68 out of 166 participants in the former control group were newly diagnosed with T2DM. The incidence of T2DM in the former diet plus physical activity group was 4.9 (95% CI 3.8 to 6.3) compared with 7.0 (95% CI 5.5 to 8.9) in the control group (DPS 2001); the HR (adjusted for sex, age, BMI and two-hour glucose) was 0.67 (95% CI 0.48 to 0.95; P = 0.023). There was a 32% relative risk reduction and a 15% absolute risk reduction during the post-intervention follow-up period in favour of the former diet plus physical activity group (DPS 2001).

Da Qing 1997 reported the incidence of T2DM after 20 and 23 years of follow-up. The HR (adjusted for age and clustering) of the former diet plus physical activity group (diet only, physical activity only, diet plus physical activity) versus control after 20

years of follow-up was 0.57 (95% CI 0.41 to 0.81). After 23 years of follow-up 312 out of 430 participants of the combined former intervention group versus 124 out of 138 participants in the former control group developed T2DM. The HR (adjusted for clustering) was 0.55 (95% CI 0.40 to 0.76; $P = 0.001$). The median delay to the onset of T2DM was 3.6 years after 20 years of follow-up.

During the first seven years the incidence of T2DM in the Diabetes Prevention Program Outcomes Study (DPPOS) compared with the incidence of T2DM in the Diabetes Prevention Program (DPP) decreased in the control group (-42%) (HR 0.58, 95% CI 0.48 to 0.69) compared with the incidence in the former diet plus physical activity group (31%) group (HR 1.31, 95% CI 1.07 to 1.61) (see [DPP 2002](#)). After 15 years of follow-up in the DPPOS the incidence of T2DM was reduced by 27% in the former diet plus physical activity group (HR 0.73, 95% CI 0.65 to 0.83; $P < 0.0001$) ([DPP 2002](#)). Over the 15 years of follow-up the average annual T2DM incidence rate was 5.2% in the former diet plus physical activity group and 7.0% in the former control group. At year 15, the cumulative incidence of T2DM was 562 participants (62%) in the former control group versus 480 participants (55%) in the former diet plus physical activity group ([DPP 2002](#)). The median delay to onset of T2DM after 10 years was about four years by diet plus physical activity compared with control. After 10 years of follow-up (i.e. about seven years after the intervention period had stopped) 23% in the former diet plus physical activity group compared with 19% in the former control group had become normoglycaemic (fasting glucose < 6.1 mmol/L, two-hour glucose < 7.8 mmol/L, and no previous diagnosis of T2DM) ([DPP 2002](#)). The annual incidence of T2DM in the diet plus physical activity group rose slowly through year 4 after randomisation, then declined to steady levels at year 7. The control group had the highest incidence of T2DM early in the DPP, with a relatively steady decline through the end of the DPP and into the DPPOS, and levelling late in the DPPOS. Post hoc analysis defining T2DM by HbA1c at 6.5% or higher showed that the incidence rate was reduced with diet plus physical activity compared with control during the DPP (4.6 cases/100 person years versus 8.8 cases/100 person years) and at 10 years of follow-up (3.5 cases/100 person years versus 5.0 cases/100 person years) ([DPP 2002](#)). Only participants with HbA1c less than 6.5% at baseline were included in this post hoc analysis (diet plus physical activity $N = 932$ at baseline; control $N = 922$ at baseline) ([DPP 2002](#)). During the total follow-up period there were differences among ethnic groups in the incidence of diabetes defined as HbA1c 6.5% or higher or FPG 7.0 mmol/L or higher and/or two-hour plasma glucose 11.1 mmol/L or higher ([Appendix 19](#)). Only 26% of the participants diagnosed with T2DM according to FPG or glucose values after an OGTT had previous or simultaneous HbA1c 6.5% or higher. On the other hand, 55% of those first attaining an HbA1c 6.5% or higher had current or previous diagnosis of T2DM defined according to FPG 7.0 mmol/L or higher and/or two-hour plasma

glucose 11.1 mmol/L or higher ([DPP 2002](#)).

Serious adverse events

Two trials reported serious adverse events ([Da Qing 1997](#); [EDIPS 2009](#)). In one trial the investigators provided information that one out of 51 participants in the diet plus physical activity group compared with none out of 51 participants in the control group experienced a serious adverse event ([EDIPS 2009](#)). The other trial reported that no adverse events were experienced in the intervention arms (low-quality evidence) ([Da Qing 1997](#)) ([Analysis 2.29](#)). Four other trials clearly described recording serious adverse events but they did not present any data ([DPP 2002](#); [HELP PD 2011](#); [IDPP 2006](#); [JDPP 2013](#)). In [DPP 2002](#) only serious adverse events related to metformin were reported for each trial arm. We could not perform any meta-analysis or subgroup analysis due to lack of data.

Secondary outcomes

Cardiovascular mortality

Seven trials reported data on cardiovascular mortality ([Da Qing 1997](#); [DPP 2002](#); [EDIPS 2009](#); [HELP PD 2011](#); [IDPP 2006](#); [JDPP 2013](#); [Oldroyd 2005](#)). Four of the trials reported that none of the participants died due to cardiovascular disease ([EDIPS 2009](#); [HELP PD 2011](#); [IDPP 2006](#); [JDPP 2013](#)). The number of participants who died due to cardiovascular disease was low (four out of 1626 participants in the diet plus physical activity group compared with four out of 1637 participants in the control group) (RR 0.94, 95% CI 0.24 to 3.65; $P = 0.93$; 3263 participants, 7 trials; very low-quality evidence). The 95% prediction interval was not meaningful ([Analysis 2.14](#)).

TSA showed that 0.13% of the diversity-adjusted information size was accrued to detect or reject a 10% RRR. Diversity was zero, but we applied a diversity of 20% when calculating the diversity-required information size as heterogeneity is likely to increase when future trials are included. As only a minor fraction of the diversity-adjusted required information size to detect or reject a 10% RRR was accrued, we could not calculate the TSA-adjusted 95% CIs with a diversity at 20%. Applying diversity at 0%, 0.16% of the diversity-adjusted information size was accrued to detect or reject a 10% RRR. Still, we could not calculate the TSA-adjusted 95% CIs.

We did not perform subgroup or sensitivity analyses due to lack of data.

One trial reported cardiovascular mortality after the intervention period had stopped ([Da Qing 1997](#)). The trial reported the HR (adjusted for age and clustering) after a total follow-up period of 20 years (i.e. 14 years after the intervention had stopped) for the combined former diet only, physical activity only and diet plus physical activity group versus former control to be 0.83 (95% CI

0.48 to 1.05). After 23 years of follow-up 78 participants died as a result of cardiovascular disease; 51 in the combined former intervention groups versus 27 in the former control group (when adjusting for clustering 29 versus 15). Cumulative incidences were 11.9% (95% CI 8.8 to 15.0) versus 19.6% (95% CI 12.9 to 26.3; the HR (adjusted for age and clustering) was 0.59 (95% CI 0.36 to 0.96; $P = 0.03$). Post hoc analyses comparing women with men after 23 years of follow-up showed a HR of 0.28 (95% CI to 0.11 to 0.71; $P = 0.01$) and 0.91 (95% CI 0.50 to 1.65), respectively (Da Qing 1997).

Non-fatal myocardial infarction

None of the trials reported non-fatal myocardial infarction at the end of the intervention period. However, the investigators of one of the included trials reported that none of the participants in the diet plus physical activity group or the standard treatment group (51 participants in each intervention group) had a non-fatal myocardial infarction (EDIPS 2009) - low quality evidence.

The DPP reported the total number of non-fatal cardiovascular events at the end of the intervention. Non-fatal cardiovascular events occurred in 24 out of 1079 participants (2.2%) (incidence rate 9.7 events per 1000 patient-years) in the diet plus physical activity group compared with 18 out of 1082 participants (1.7%) with an incidence rate of 7.3 events per 1000 patient-years in the control group. No substantial differences were seen in the diet plus physical activity group compared with standard treatment (DPP 2002). The excess of events in the diet plus physical activity group was due to hospitalisations because of cardiovascular disease and revascularisation procedures (DPP 2002).

The IDPP also only reported the total number of cardiovascular events with four (3.3%) out of 120 participants in the diet plus physical activity group compared with two (1.5%) out of 133 participants in the control group (IDPP 2006).

Da Qing 1997 reported a cumulative incidence of any first cardiovascular event to be 5.2 (95% CI 3.0 to 7.3) in the combined intervention group (diet only, physical activity only, diet plus physical activity) compared with 5.4 (95% CI 1.5 to 9.2) in the control group during the intervention period. The incidence rate per 100 person years was 0.9 (95% CI 0.2 to 1.6) in the intervention group compared with 0.9 (95% CI 0.5 to 1.3) in the control group during the intervention period. The HR adjusted for age and clustering was 0.96 (95% CI 0.76 to 1.44).

From one trial it was apparent that cardiovascular event data were collected during the intervention period, but no data were reported (DPS 2001).

Two trials reported cardiovascular complications after the intervention period had stopped (Da Qing 1997; DPS 2001). One trial reported composite cardiovascular morbidity after a total follow-up of 10.6 years (i.e. about 6.6 years after the end of intervention); 57 cardiovascular events were reported in 257 participants of the former diet plus physical activity group compared with 54 events

in 248 participants in the former control group (DPS 2001). The incidence rate of cardiovascular morbidity was 22.9 in the former diet plus physical activity group versus 22.0 per 1000 person years in the former control group; the HR was 1.04 (95% CI 0.72 to 1.51). Men and women had the same incidence in the two intervention groups (DPS 2001). Da Qing 1997 reported the cumulative incidence of any first cardiovascular event to be 40.9 (95% CI 36.0 to 45.9) in the combined former intervention group (diet only, physical activity only, diet plus physical activity) compared with 44.1 (95% CI 35.3 to 53.0) in the former control group after a total follow-up period of 20 years (i.e. 14 years after the intervention had stopped). The incidence rate per 100 person years was 2.3 (95% CI 1.9 to 2.7) in the intervention group compared with 2.5 (95% CI 1.9 to 3.2) in the control group after 20 years of follow-up. The HR adjusted for age and clustering was 0.98 (95% CI 0.71 to 1.37) (Da Qing 1997).

Non-fatal stroke

None of the trials reported non-fatal stroke at the end of the intervention period. However, the investigators of one of the included trials reported that none of the participants in the diet plus physical activity or the control group (51 participants in each intervention group) had a non-fatal stroke (EDIPS 2009) - low quality evidence.

Several trials reported data on composite cardiovascular events (see above) (DPP 2002; Da Qing 1997; IDPP 2006).

Amputation of lower extremity

None of the trials reported amputation of the lower extremity at the end of the intervention period. However, the investigators of one of the included trials reported that none of the participants in the diet plus physical activity or the control group (51 participants in each intervention group) had an amputation of the lower extremity (EDIPS 2009).

Several trials reported data on composite cardiovascular events (see above) (DPP 2002; Da Qing 1997; IDPP 2006).

Blindness or severe vision loss

We did not identify trials with data on blindness or severe vision loss for this comparison.

One trial reported severe retinopathy after 20 years of follow-up. Severe retinopathy occurred in 31 participants out of 238 in the intervention group (cumulative incidence 9.2%) compared with 17 out of 93 in the control group (cumulative incidence 16.2%) (Da Qing 1997). The HR (adjusted for clustering and age) was 0.53 (95% CI 0.29 to 0.99; $P = 0.048$) in favour of the intervention (Da Qing 1997). All participants with severe retinopathy had developed T2DM by the time the retinopathy was recognised (Da Qing 1997).

One trial reported an aggregate outcome of microvascular disease (nephropathy, retinopathy and neuropathy) after 15 years of follow-up (DPP 2002). The prevalence of microvascular outcomes after 15 years did not differ substantially between the intervention and control group despite group differences in the incidence of T2DM (former diet plus physical activity group 11.3% (95% CI 10.1 to 12.7) compared with former control 12.4% (95% CI 11.1 to 13.8)). The women but not the men in the former diet plus physical activity group experienced a reduction in microvascular disease (RR 0.79, 95% CI 0.64 to 0.98) compared with the former control group. There were no substantial differences in the treatment effects on aggregate microvascular complications in subgroups defined by age or ethnicity, except that Hispanic Americans had a lower microvascular disease prevalence in the former diet plus physical activity group than in the former control group (RR 0.43, 95% CI 0.20 to 0.91) (DPP 2002).

End-stage renal disease

None of the trials reported end-stage renal disease at the end of the intervention period.

One trial reported renal replacement therapy or death due to kidney failure after 20 years of follow-up (i.e. 14 years after the intervention had stopped). Seven out of 441 participants (when adjusting for clustering; 4 out of 252 participants) of the combined former intervention group compared with two out of 136 participants (when adjusting for clustering 1 out of 78 participants) in the former control group developed end-stage renal disease (Da Qing 1997).

Non-serious adverse events

One trial reported that no non-serious adverse events were reported (diet plus physical activity 0/126 (adjusted for clustering 0/72 versus control 0/76)) (Da Qing 1997). Another trial reported three (3.6%) out of 84 participants in the diet plus physical activity group compared with four (4.8%) out of 83 participants in the control group experienced a non-serious adverse event (PODOSA 2014).

Hypoglycaemia

Two trials reported that none of the participants experienced hypoglycaemia (IDPP 2006: diet plus physical activity 0/133 compared with control 0/136; EDIPS 2009: diet plus physical activity 0/51 compared with control 0/51).

Health-related quality of life

The DPP trial applied the 36-item Short-Form (SF-36) to evaluate the health utility index (SF-6D), physical component summaries

(PCS) and mental component summaries (MCS). Minimal important difference (MID) was defined as a difference in scores between groups of at least 3% (DPP 2002). A total of 1070 participants from the diet plus physical activity group and 1074 participants from the standard treatment group were included (DPP 2002). In both the diet plus physical activity arm as well as the control arm HrQoL summary scores worsened during the trial, but the decline for SF-6D ($P < 0.05$) and PCS ($P < 0.01$) was slower in diet plus physical activity participants compared to the changes in the control group; however, none reached the MID of 3%. After a mean of 3.2 years of follow-up there were improvements in the SF-6D (0.008; $P = 0.04$) in the diet plus physical activity group compared with control, however, the MID of 3% between the intervention groups was not achieved. The PCS (1.57; $P < 0.0001$) also improved in the diet plus physical activity group compared with control (DPP 2002). Again, the MID between the intervention groups was not achieved. MCS improved in the placebo group compared with the diet plus physical activity group during the intervention period with 0.28 (SD 0.32). No exact P -value was provided, the value was more than 5%. The MID was not achieved (DPP 2002). The overall quality of evidence for this outcome measure was very low.

The investigators from the PODOSA 2014 reported that the participants were asked how healthy they were during the trial. The replies were not analysed at the end of the intervention.

One trial stated in the design article that HrQoL measured with the SF-36 would be assessed. However, no data were available (HELP PD 2011). One publication stated that HrQoL was measured, but no data were reported (EDIPS 2009). According to the investigators HrQoL was not analysed (EDIPS 2009).

Time to progression to type 2 diabetes

One trial reported data on the time to progression to T2DM in the post-interventional follow-up period (median of seven years). Among the participants who developed T2DM the median time to the onset of T2DM was 15 years (95% CI 13 to 17) in the former intervention group compared with 10 years (95% CI 8 to 12 years) in the former control group (95% CI 8 to 12 years) (DPS 2001).

Measures of blood glucose control

Fasting glucose

Ten trials reported FPG (Da Qing 1997; DPP 2002; DPS 2001; EDIPS 2009; HELP PD 2011; IDPP 2006; JDPP 2013; Oldroyd 2005; PODOSA 2014; SLIM 2003). Effect-estimates in both random-effects and fixed-effect models showed differences (random MD -0.17 mmol/L, 95% CI -0.27 to -0.06; $P = 0.003$; fixed MD -0.21 mmol/L, 95% CI -0.27 to -0.15; $P < 0.00001$; 10 trials;

3530 participants; [Analysis 2.18](#)). The 95% prediction interval ranged between -0.43 mmol/L to 0.09 mmol/L.

TSA showed that diversity-adjusted information size was accrued to detect or reject a difference in fasting plasma glucose at -0.17 mmol/L in favour of the diet plus physical activity group. Diversity was 70%.

Subgroup analyses: according to duration of the intervention (≥ 4 years) versus trials with short duration (< 4 years)), diagnostic criteria of participants with IGT versus other; age (included participants ≥ 50 years versus < 50 years); ethnicity (Asian versus predominantly White); morbidity (BMI ≥ 30 kg/m² versus < 30 kg/m²); showed no statistically significant interactions ([Appendix 18](#)). We could not perform subgroup analyses according to sex and previous gestational diabetes due to lack of data.

Sensitivity analysis: we could not perform sensitivity analyses according to publication status and language of publication as all included trials were published in English. Sensitivity analysis restricted to trials with low risk of selection bias showed a MD of -0.14 mmol/L (95% CI -0.26 to -0.01; $P = 0.03$) ([DPP 2002](#); [DPS 2001](#); [EDIPS 2009](#); [HELP PD 2011](#); [JDPP 2013](#); [Oldroyd 2005](#); [PODOSA 2014](#)). Analysing trials according to geographies for trials performed in Asia showed a MD of -0.18 mmol/L (95% CI -0.49 to 0.13; $P = 0.15$) ([Da Qing 1997](#); [IDPP 2006](#); [JDPP 2013](#)). Trials performed in Europe showed a MD of -0.08 mmol/L (95% CI -0.80 to 0.08; $P = 0.15$) ([DPS 2001](#); [EDIPS 2009](#); [Oldroyd 2005](#); [PODOSA 2014](#); [SLIM 2003](#)). One trial reported FPG after 20 years of follow-up ([Da Qing 1997](#)). The mean FPG was 7.9 (SD 3.2) in 260 participants (149 participants when adjusting for clustering) in the combined former intervention groups compared with 8.7 (SD 3.1) in 80 participants (46 participants when adjusting for clustering) in the former control group ([Da Qing 1997](#)). Another trial reported FPG after 15 years of follow-up. FPG was 6.8 mmol/L (SD 2.0) in 751 participants in the former diet plus physical activity group compared with 6.8 mmol/L (SD 1.9) in 780 participants in the former control group ([DPP 2002](#)).

Glucose two hours after an oral glucose load

Nine trials reported glucose values two hours after an oral glucose load ([Da Qing 1997](#); [DPP 2002](#); [DPS 2001](#); [EDIPS 2009](#); [IDPP 2006](#); [JDPP 2013](#); [Oldroyd 2005](#); [PODOSA 2014](#); [SLIM 2003](#)). Two hours after an oral glucose load glucose values were higher in the control group compared with the diet plus physical activity group (random MD -0.46 mmol/L, 95% CI -0.79 to -0.12; $P = 0.008$; fixed MD -0.29 mmol/L, 95% CI -0.44 to -0.15; $P < 0.00001$; 9 trials; 3261 participants; [Analysis 2.24](#)). The 95% prediction interval ranged between -1.41 mmol/L to 0.49 mmol/L.

TSA showed that diversity-adjusted information size was accrued to detect or reject a difference in two-hour plasma glucose at -

0.46 mmol/L in favour of the diet plus physical activity group. Diversity was 82%.

Subgroup analyses: according to duration of the intervention (≥ 4 years) versus trials with short duration (< 4 years)), ethnicity (Asian versus predominantly white); morbidity (BMI ≥ 30 kg/m² versus < 30 kg/m²); showed no statistically significant interactions ([Appendix 18](#)). The subgroups of trials according to age (≥ 50 years versus < 50 years) showed significant interaction between subgroups ($P = 0.003$). However, the CIs in these analyses overlap to a small degree. As a caveat, these observations should be regarded as hypothesis-generating only. We could not perform subgroup analyses according to sex, diagnostic criteria of participants with IGT versus other and previous gestational diabetes due to lack of data.

Sensitivity analysis: we could not perform sensitivity analysis according to publication status (all included trials were published) and language of publication (all included trials were published in English). Sensitivity analysis restricted to trials with low risk of selection bias showed a MD of -0.14 mmol/L (95% CI -0.26 to -0.01; $P = 0.03$) ([DPP 2002](#); [DPS 2001](#); [EDIPS 2009](#); [JDPP 2013](#); [Oldroyd 2005](#); [PODOSA 2014](#)). Analysing trials performed in Asia showed a MD of -1.10 mmol/L (95% CI -2.3 to 0.11; $P = 0.07$) ([Da Qing 1997](#); [IDPP 2006](#); [JDPP 2013](#)). Trials performed in Europe showed a MD of -0.35 mmol/L (95% CI -0.78 to 0.08; $P = 0.11$) ([DPS 2001](#); [EDIPS 2009](#); [Oldroyd 2005](#); [PODOSA 2014](#)).

One trial reported glucose values two hours after an OGTT after 20 years of follow-up ([Da Qing 1997](#)). The mean two-hour glucose value was 11.5 mmol/L (SD 5.0) in 100 participants (57 participants when adjusting for clustering) in the combined former intervention groups compared with 13.8 mmol/L (SD 5.8) in 28 participants (16 participants when adjusting for clustering) in the former control group ([Da Qing 1997](#)).

HbA1c

Four trials reported data on HbA1c ([DPP 2002](#); [DPS 2001](#); [EDIPS 2009](#); [SLIM 2003](#)).

In the random-effects model the MD was -0.11% (95% CI -0.23 to 0.02; $P = 0.09$; 4 trials; 2453 participants) ([Analysis 2.31](#)), in the fixed-effect model the MD was -0.18%, 95% CI -0.23 to -0.13; $P < 0.00001$). The 95% prediction interval ranged between -1.64% and 1.42%.

TSA showed that 36.5% diversity-adjusted information size was accrued to detect or reject a HbA1c difference of -0.11% between the intervention groups. Alfa-spending-adjusted 95% CI was -0.34 to 0.12. Diversity was 86%.

Subgroup analysis: analysing trials according to the duration of the intervention (≥ 4 years) versus trials with short duration (< 4 years) showed no interaction between subgroups ($P = 0.99$) ([Analysis 2.34](#); [Appendix 18](#)). Analysing trials according to the BMI ≥ 30 kg/m² versus < 30 kg/m² showed no interaction between

subgroups ($P = 0.10$) (Analysis 2.35). All trials reporting HbA1c included people with IGT, all included participants aged 50 years or more, and all included only white or mainly white people (DPP 2002; DPS 2001; EDIPS 2009; SLIM 2003).

Sensitivity analysis: we could not perform sensitivity analysis according to publication status (all included trials were published) and language of publication (all included trials were published in English). Sensitivity analysis restricted to only trials with low risk of selection bias showed MD -0.15%, 95% CI -0.27 to -0.04; $P = 0.009$ (DPP 2002; DPS 2001; EDIPS 2009). Analysing trials according to geographies in trials performed in Europe showed a MD of -0.02%, 95% CI -0.26 to 0.21; $P = 0.84$ (DPS 2001; EDIPS 2009; SLIM 2003).

One trial reported the HbA1c after 20 years of follow-up (Da Qing 1997). The mean HbA1c was 7.34% (SD 1.7) in 271 participants (155 participants when adjusting for clustering) in the combined former intervention group compared with 7.83% (SD 2.0) in 81 participants (46 participants when adjusting for clustering) in the former control group (Da Qing 1997). Another trial reported the HbA1c after 15 years of follow-up. The mean HbA1c was 6.2% (SD 1.2) in 751 participants in the former diet plus physical activity group compared with 6.3% (SD 1.2) in 780 participants in the former control group (DPP 2002).

Socioeconomic effects

During DPP 2002, the diet plus physical activity groups were substantially more expensive than the standard treatment intervention. Direct medical costs of the interventions during the DPP were estimated to be USD 3628 for the diet plus physical activity group versus USD 184 for the control group. Direct medical costs (hospital days, emergency room visits, urgent care visits, outpatient visits, calls to providers, supplies, laboratory tests, and pre-

scription medications within the intervention groups) outside the DPP were estimated to be USD 5182 for the diet plus physical activity group compared with USD 5680 for the control group. However, due to the high direct medical costs of T2DM, the diet plus physical activity intervention was estimated to be cost-effective. The quality of evidence was low. From the perspective of the health system (direct medical costs of the interventions plus direct medical costs of care outside the trial) the cost was USD 31,500 per quality-adjusted life years (QALY) gained with diet plus physical activity compared with control. From the perspective of society (direct medical costs plus non medical costs (expenditure on medical treatment but not involving purchase of medical services or products) plus indirect costs (costs to society due to morbidity and mortality, e.g. absent from work due to medical treatment)) the cost was USD 51,600 per QALY gained with diet plus physical activity compared with control.

PODOSA 2014 reported that the extra mean cost for the diet plus physical activity group was GBP 1126 (95% CI -2414 to 4666) after three years, with GBP 615 of the difference being dietitian costs. Primary-care visits and costs did not differ between groups, but there were more outpatient visits in the intervention group (costing GBP 327 more than in the control group).

IDPP 2006 estimated direct medical costs of interventions over the three-year trial period to be USD 61 per participant in the control group compared with USD 225 in the diet plus physical activity group. The cost-effectiveness to prevent one case of diabetes with diet plus physical activity was USD 1052.

In HELP PD 2011, direct medical costs for each participant in the diet plus physical activity group were USD 850 compared with USD 142 in the control group. Direct costs of care outside the trial were USD 5177 for the diet plus physical activity group compared with USD 7454 for the control group.

The overall quality of evidence was low for this outcome measure.

ADDITIONAL SUMMARY OF FINDINGS *[Explanation]*

Diet versus physical activity or standard treatment for prevention or delay of type 2 diabetes mellitus						
<p>Population: people at increased risk of developing type 2 diabetes mellitus Settings: outpatients Intervention: dietary intervention Comparison: physical activity or standard treatment</p>						
Outcomes	Physical activity	Diet or standard treatment	Relative effect (95% CI)	No of participants (trials)	Quality of the evidence (GRADE)	Comments
All-cause mortality Follow-up: 6 years	See comment	See comment	See comment	530 (1)	⊕○○○ very low^a	3/130 participants died in the diet group vs 0/141 participants in the physical activity group 3/133 participants died in the standard treatment group
Incidence of type 2 diabetes mellitus Definition: WHO 1985 criteria Follow-up: 6 years	See comment	See comment	See comment	530 (1)	⊕○○○ very low^a	57/130 participants developed T2DM in the diet group vs 58/141 participants in the physical activity group 90/133 participants developed T2DM in the standard treatment group
Serious adverse events Follow-up: 6 years	See comment	See comment	See comment	530 (1)	⊕○○○ very low^a	No (serious) adverse events occurred in any group
Cardiovascular mortality Follow-up: 6 years	See comment	See comment	See comment	530 (1)	⊕○○○ very low^a	No participants in any group died of cardiovascular reasons

Non-fatal myocardial infarction/stroke	Not reported
Health-related quality of life	Not reported
Socioeconomic effects	Not reported
<p>*The basis for the assumed risk (e.g. the median control group risk across studies) is provided in footnotes. The corresponding risk (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI). CI: confidence interval; RR: risk ratio; T2DM: type 2 diabetes mellitus; WHO: World Health Organization</p>	
<p>GRADE Working Group grades of evidence High quality: we are very confident that the true effect lies close to that of the estimate of the effect. Moderate quality: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of effect, but there is a possibility that it is substantially different. Low quality: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of effect, but there is a possibility that it is substantially different. Very low quality: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect</p>	

*Assumed risk was derived from the event rates in the comparator groups

^aDowngraded by three levels because of risk of reporting and other bias and serious imprecision (very sparse data) - see [Appendix 15](#)

Physical activity versus standard treatment for prevention or delay of type 2 diabetes mellitus						
Population: people at increased risk of developing type 2 diabetes mellitus Settings: outpatients Intervention: physical activity Comparison: standard treatment

						ical activity group compared with 1/31 participants in the standard treatment group experienced a non-fatal stroke (Hellgren 2016 - data provided by trial authors)
Health-related quality of life Definition: measured by two questions (grading total physical and mental health from 1 to 7; grading general health from 1 (best) to 5 (very bad)) Follow-up: 3 years	See comment	See comment	See comment	123 (1)	⊕○○○ very low ^a	27%, 43% and 29% of participants in the physical activity group experienced worse, unchanged and better health-related quality of life, respectively (Hellgren 2016 - data provided by trial authors) 35%, 43% and 22% in the standard treatment group experienced worse, unchanged and better health-related quality of life, respectively (Hellgren 2016 - data provided by trial authors)
Socioeconomic effects	Not reported					
<p>*The basis for the assumed risk (e.g. the median control group risk across studies) is provided in footnotes. The corresponding risk (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI). CI: confidence interval; FPG: fasting plasma glucose; OGTT: oral glucose tolerance test; RR: risk ratio; T2DM: type 2 diabetes mellitus</p>						
<p>GRADE Working Group grades of evidence High quality: we are very confident that the true effect lies close to that of the estimate of the effect. Moderate quality: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of effect, but there is a possibility that it is substantially different. Low quality: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of effect, but there is a possibility that it is substantially different. Very low quality: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect</p>						

*Assumed risk was derived from the event rates in the comparator groups

^aDowngraded by three levels because of risk of reporting and other bias and serious imprecision (very sparse data) - see

[Appendix 16](#)

DISCUSSION

Summary of main results

This Cochrane Review investigated the effects of diet or physical activity, or both in people at increased risk of developing T2DM. We included 12 trials with a total of 5238 participants. We judged all trials as at unclear or high risk of bias in one or more 'Risk of bias' domains. The amount of evidence on patient-important outcomes was limited. The meta-analysis comparing diet plus physical activity with standard or no treatment showed moderate-quality evidence of a reduced incidence of T2DM after the end of the intervention. The diversity-adjusted required information size of TSA to confirm a 10% RRR was reached. The reporting on mortality and macrovascular as well as microvascular diabetes complications was insufficient and we judged the quality of evidence for these outcome measures as low or very low.

Overall completeness and applicability of evidence

The diagnosis of intermediate hyperglycaemia varied among trials and some trials used a definition that may have included participants judged to be euglycaemic or having T2DM. However, all trials except one had IGT as an inclusion criterion (HELP PD 2011). The results of this review might therefore not be applicable to people defined by other glycaemic categories of intermediate hyperglycaemia.

Detailed information about the participants was lacking in most trials. The included trials applied different intensities of diet and physical activity. In our review, all programmes were conducted in adults. Therefore, our results may not apply to children and adolescents. A potential selection bias exists as more healthy and motivated people may participate in a clinical trial. However, a Cochrane Review observed that clinical outcomes in people participating in RCTs are comparable to similar individuals outside trials (Vist 2008). However, the implementation of diet and physical activity programmes outside a clinical trial often shows less pronounced effects in surrogate markers (e.g. glycaemic measures) (Ashra 2015).

Three of the included trials contributed about 70% of all data (Da Qing 1997; DPP 2002; DPS 2001). Reporting of complications associated with T2DM during the intervention period was lacking. However, after 23 years of follow-up, all-cause mortality and cardiovascular mortality were reduced in one study (Da Qing 1997). This effect was only found in women. However, the trial found a delay in the onset of T2DM of 3.6 years (Da Qing 1997). The only data on microvascular complications were available after an extended follow-up period. There was discrepancy in the long-term effects of the diet plus physical activity intervention in the

DPP 2002 and the Da Qing 1997 follow-up. Da Qing 1997 reported a reduction of severe retinopathy after 20 years of follow-up in the former intervention group (HR 0.53, 95% CI 0.29 to 0.99; $P = 0.048$). In DPP 2002 there was no influence on microvascular outcomes after 15 years of follow-up.

The three major trials all included people with IGT. Unfortunately, similar trials have not been performed in people with IFG or moderately elevated HbA1c. One of the excluded trials included 379 overweight Japanese people with IFG only. However, the intervention group and the control group received similar diet and physical activity advice, but with less frequent visits in the control group, and was consequently not included in this review (Saito 2011). The trial did not find an impact on the risk of T2DM in participants with isolated IFG after 36 months of intervention (HR 1.17, 95% CI 0.50 to 2.74) (Saito 2011). However, because of the technical complexities of performing an OGTT compared with measuring fasting glucose or HbA1c, most people with intermediate hyperglycaemia are expected to be diagnosed with these modalities (International Expert Committee 2009). It is therefore unclear whether similar effects in reducing or delaying T2DM incidence will be found in the majority of people with intermediate hyperglycaemia.

The number of participants diagnosed with T2DM in the control groups in the included trials was higher than that estimated from observational studies (Cheng 2006; Morris 2013). This might be explained by the regular glycaemic testing of people participating in a RCT. Therefore, many of those diagnosed with T2DM in a RCT may not be diagnosed in a 'real-world' setting.

Most trials included participants aged above 50 years. In both DPP 2002 and DPS 2001, diet plus physical activity was most effective in reducing T2DM incidence in people aged 60 years or more. A person aged 65 years or more with newly diagnosed T2DM with a HbA1c of 7% has a theoretical life-time risk of blindness or end-stage renal disease of less than 0.5% (Vijan 1997). The reason for the lack of reliable data on diabetic complications T2DM in our review might be explained by the low rate of these complications in the people with the largest intervention effect and the time it takes to develop these complications (Vijan 1997).

In all trials reporting the direct costs of the diet and physical activity programmes, the intervention was significantly more expensive than control (DPP 2002; EDIPS 2009; HELP PD 2011; IDPP 2006). However, the diet plus physical activity intervention programmes were estimated to be cost-effective due to the reduction of T2DM with these programmes (DPP 2002). On the other hand, the interventions in the included trials would be challenging and costly to implement in daily life. In general, the adherence to diet and lifestyle advice was low in the included trials, and might even be lower in a non-trial setting. A more cost-effective and long-lasting solution could be to enable people to undertake physical activity as part of their everyday life, and regulation of food costs. Not only people with intermediate hyperglycaemia but also people with manifest T2DM are recommended to increase physical

activity and lower calorie intake (ADA 2017). However, the only long-term RCT assessing the effects of diet plus physical activity in people with T2DM was stopped early due to futility after a median follow-up of 9.6 years (Look AHEAD 2013). In addition, long-term follow-up data for DPP 2002 have not shown any substantial effect on mortality or diabetes-related complications after 15 years of follow-up, even though the incidence of T2DM was reduced with the diet plus physical activity intervention.

Quality of the evidence

For all trials, we contacted one or more trial authors to obtain supplemental information on baseline data, bias domains and outcomes. In addition, we asked investigators to confirm our extracted outcomes. Unfortunately only four investigators (33%) of the included trials either just confirmed a question or provided additional data that could be implemented for the 'Risk of bias' assessment or the meta-analyses of outcomes (EDIPS 2009; Hellgren 2016; IDPP 2006; PODOSA 2014).

We included trials with an intervention duration of two years or more. Trials with shorter duration could have been included, but as we were focusing on patient-important outcomes we did not include such short-term studies (D-CLIP; DH!AAN; Hesselink 2013; Huang 2007; J-DOIT; Kawahara 2008; Kinmonth 2008; Lindahl 1999; Marrero 2016; Page 1992; Ramachandran 2013; Sathish 2017; Savoye 2007; Thompson 2008; Villareal 2006; Yates 2011).

None of the 11 included trials in our review was classified as having low risk of bias in all 'Risk of bias' domains. The description of randomisation and allocation was insufficient in 33% of the included trials (Da Qing 1997; IDPP 2006; Kosaka 2005; SLIM 2003). Only one trial was classified as having low risk of bias for selective outcome reporting (Hellgren 2016). The remaining trials had insufficient reporting of one or more outcomes of relevance to our review. However, we were able to assess one or more of our predefined outcomes in all of the included trials.

For the comparisons 'diet only versus comparator' and 'physical activity only versus comparator', we judged the quality of evidence to be very low because of sparse data and various risks of bias. For the comparison 'diet plus physical activity' more data were available. However, again most outcome measures were associated with low- or very low-quality evidence.

Potential biases in the review process

We were unable to draw funnel plots to assess small-study bias due to lack of data for most outcomes. However, for one of our primary outcomes - the incidence of T2DM - we were able to draw a funnel plot, which did not indicate publication bias. If more data had been available on the patient-important outcomes of our review, we would have performed more meta-analyses. Many of

the included trials were not designed or powered to detect our predefined patient-important outcomes. For the performed meta-analyses we investigated heterogeneity and the potential reasons for it through subgroup and sensitivity analyses. We were dealing with a substantially heterogeneous group of trials. Our meta-analyses were limited by the inability to use individual participant data to assess whether distinct clinical characteristics may have influenced the effect estimates of the interventions. To reduce the risk of random errors, we conducted TSA on all predefined outcomes and calculated prediction intervals, whenever possible. We contacted all trial authors for clarification if one of the bias domains was not adequately reported. Several trials were published in more than one publication, which for some trials made it difficult to separate the primary publication from companion papers. We excluded trials including participants with IGT due to other conditions (e.g. cystic fibrosis or glucocorticoid treatment). We included trials with a minimum duration of two years in order to detect clinically relevant differences for the predefined outcomes. Even though we focused on long-term trials, the reporting of clinical outcomes in the included trials was poor. Two review authors carried out data extraction. However, the review authors extracting the data were not blinded as to which trial they were extracting data from.

Agreements and disagreements with other studies or reviews

We conducted an extensive search for trials, including publications in all languages and tried to obtain additional data on all trials. Investigators of three trials provided additional information (EDIPS 2009; Hellgren 2016; PODOSA 2014). We looked for additional trials and cross-checked our data with other meta-analyses and Cochrane Reviews of relevance (Aguiar 2014; Ali 2012; Ashra 2015; Balk 2015; Cardona-Morrell 2010; Dunkley 2014; Gillett 2012; Gillies 2007; Glechner 2015; Gong 2015; Hopper 2011; ICER 2016; Merlotti 2014a; Merlotti 2014b; Modesti 2016; Norris 2005; Santaguida 2005; Schellenberg 2013; Selph 2015; Stevens 2015; Yamaoka 2005; Yates 2007; Yoon 2013; Yuen 2010; Zhang 2017; Zheng 2016). However, several publications defined the increased risk of T2DM development to be associated with additional covariates, with intermediate hyperglycaemia being only one risk factor (e.g. obesity, metabolic risk factors, family history of diabetes - Ali 2012; Ashra 2015; Balk 2015; Cardona-Morrell 2010; Dunkley 2014; Merlotti 2014a; Merlotti 2014b; Modesti 2016; Schellenberg 2013; Zhang 2017). Furthermore, these systematic reviews excluded trials with the same intensity in diet and physical activity, where the only difference between the intervention arms was the approach on how to motivate the participants. We excluded these trials (e.g. evaluating mobile text messages versus individual sessions, or one visit a year versus four visits a year) because this setting addresses another research question, and it is important to clarify whether the interventions work as such. Also, our review is the first focusing on patient-important out-

comes. Therefore, we only included trials with an intervention duration of two years or more. Even though we focused on longer-term trials, the reporting on patient-important outcomes was still lacking. Observational data of trials with extended follow-up periods could also not prove long-term beneficial effects regarding patient-important outcomes (DPP 2002; DPS 2001). The only trial reporting long-term benefits was Da Qing 1997, however, few participants were included in the analyses. In addition, these observational extension periods of interventional trials need to be interpreted with caution because the long-term cohort may not be comparable with the originally randomised participants.

AUTHORS' CONCLUSIONS

Implications for practice

There is moderate-quality evidence that diet plus physical activity reduces or delays the risk of type 2 diabetes mellitus in people with impaired glucose tolerance. Whether there is the same intervention effect in people with increased risk defined by other glycaemic variables, such as impaired fasting glucose or elevated glycosylated haemoglobin A1c (HbA1c) levels, needs to be clarified. There is no clear evidence whether diet alone or physical ac-

tivity alone influences the risk of type 2 diabetes mellitus. Data on patient-important outcomes such as mortality, macrovascular and microvascular diabetic complications and health-related quality of life are sparse.

Implications for research

It remains to be clarified whether the reduction in the incidence of type 2 diabetes mellitus with diet plus physical activity in people with impaired glucose tolerance could decrease the long-term risk of complications associated with type 2 diabetes mellitus. Future trials should also investigate the effect of diet plus physical activity in people with impaired fasting glucose or moderately elevated HbA1c and focus on patient-important outcomes.

ACKNOWLEDGEMENTS

We thank Erika Ota for evaluating the Japanese reference of the Japan Diabetes Prevention Program (JDPP 2013). We thank Anne Douglas for confirming and providing data on the PODOSA 2014 trial, Linda Penn for confirming and providing data for the EDIPS 2009 trial and Margaretha Hellgren for confirming and providing data for the Hellgren 2016 trial.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Da Qing 1997

Methods	Cluster-randomised, controlled, clinical trial, randomisation ratio 1:1:1:1	
Participants	Inclusion criteria: IGT (WHO 1985) Exclusion criteria: - Diagnostic criteria: 2-h plasma glucose after an OGTT ≥ 7.8 mmol/L and < 11.1 mmol/L (WHO 1985). No explicit mention of FPG measurements, but FPG should be < 7.8 mmol/L according to the criteria suggested by the trial authors	
Interventions	Number of study centres: 33 healthcare clinics Treatment before study: none Run-in period: none Extension period: yes, extended follow-up 17 years after the end of intervention	
Outcomes	Composite outcome measures reported: yes (Quote from publication: "CVD events were defined as the first nonfatal or fatal cardiovascular events including myocardial infarction, sudden death, stroke, or amputation")	
Study details	Trial terminated early: no	
Publication details	Language of publication: English and Chinese Funding: non-commercial funding Publication status: peer-reviewed journal	
Stated aim of study	Quote from publication: "The trial was designed as a controlled clinical trial in which subjects were randomized by clinic to investigate the incidence of diabetes in people with IGT"	
Notes	Each clinic, rather than each participant, was randomised to carry out the intervention on each of the eligible subjects attending that clinic according to one of the 4 specified intervention protocols	
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote from publication: "subjects were randomised by clinic" Comment: insufficient information about the allocation concealment
Allocation concealment (selection bias)	Unclear risk	Comment: no information. Physical activity (expressed in units/d) was significantly higher at baseline in the DPPA group than

		in the control group
Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality	Low risk	Comment: no blinding but judged that the outcome was not likely to be influenced by lack of blinding, investigator-assessed outcome measurement
Blinding of participants and personnel (performance bias) amputation, blindness/severe vision loss, end-stage renal disease	Low risk	Quote from publication: “Investigators who assessed the outcomes at follow-up were masked to treatment allocation. Patients and other investigators were not masked.” Comment: sufficient blinding of outcome assessment, investigator-assessed outcome measurement. Not assessed during the intervention period
Blinding of participants and personnel (performance bias) incidence of T2DM	Low risk	Quote from publication: “Investigators who assessed the outcomes at follow-up were masked to treatment allocation. Patients and other investigators were not masked.” Comment: sufficient blinding of outcome assessment after the end of intervention. Assume investigators were not blinded during the trial due to the design of the study. Investigator-assessed outcome measurement
Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	Comment: investigator-assessed outcome measurement. Assume investigators were not blinded during the trial due to the design of the trial. Outcome unlikely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) non-serious adverse events	High risk	Comment: investigator-assessed and self-reported outcome measurement. Assume participants and investigators were not blinded during the trial due to the design of the study. The outcome could be influenced by lack of blinding
Blinding of participants and personnel (performance bias) serious adverse events	Low risk	Comment: investigator-assessed outcome measurement. Assume investigators were not blinded during the trial due to the design of the study. Outcome unlikely to be influenced by lack of blinding

<p>Blinding of outcome assessment (detection bias) all-cause/cardiovascular mortality</p>	<p>Low risk</p>	<p>Quote from publication: “Investigators who assessed the outcomes at follow-up were masked to treatment allocation. Patients and other investigators were not masked.” and: “From a review of this information, two physicians, blinded to the participant’s intervention, independently determined and assigned the underlying cause of death. A third physician (also blinded to the intervention) settled any disagreements. Only a general classification of cause of death was used (stroke, heart disease or any other CVD, cancer, injuries, diabetes or renal, and other).”</p> <p>Comment: sufficient blinding of outcome assessment after the end of intervention. Assume investigators were not blinded during the trial due to the design of the study. Investigator-assessed outcome measurement</p>
<p>Blinding of outcome assessment (detection bias) amputation, blindness/severe vision loss, end-stage renal disease</p>	<p>Low risk</p>	<p>Quote from publication: “Investigators who assessed the outcomes at follow-up were masked to treatment allocation. Patients and other investigators were not masked.”</p> <p>Comment: sufficient blinding of outcome assessment, investigator-assessed outcome measurement. Not assessed during the intervention period</p>
<p>Blinding of outcome assessment (detection bias) measures of blood glucose control</p>	<p>Low risk</p>	<p>Comment: Investigator-assessed outcome measurement. Assume investigators were not blinded during the trial due to the design of the study. Outcome unlikely to be influenced by lack of blinding</p>
<p>Blinding of outcome assessment (detection bias) non-serious adverse events</p>	<p>Unclear risk</p>	<p>Comment: Investigator-assessed and self-reported outcome measurement. Assume participants and investigators were not blinded during the trial due to the design of the study. The outcome could be influenced by lack of blinding</p>
<p>Blinding of outcome assessment (detection bias) serious adverse events</p>	<p>Unclear risk</p>	<p>Comment: Investigator-assessed outcome measurement. Assume investigators were not blinded during the trial due to the design of the study. Outcome unlikely to be influenced by lack of blinding</p>

<p>Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality</p>	<p>Unclear risk</p>	<p>Quote from publication (extended follow-up period): “We tried to follow up all the original study participants to establish their vital status. For deceased participants, we collected date and cause of death from death certificates, reviews of medical records, and interviews with proxy informants. We asked proxy informants about the date, place, and circumstances of death along with information about hospitals or physicians from whom the participant had received care around the time of death. We obtained medical records and death certificates and, together with the informant interviews, they were reviewed and adjudicated independently by two doctors (JW and YA) to establish the underlying cause of death.”</p> <p>Quote from main publication: “Of the 577 subjects with IGT who were randomized, 530 completed the study. Of the remainder, 7 people refused follow-up, 29 left Da Qing in 1988 (mostly because of the establishment of a new oil field elsewhere), and 11 died during the course of the study.”</p> <p>Comment: not stated if they did the same to establish mortality status at the end of intervention period. Not reported to which group the 29 participants who left the trial were randomised</p>
<p>Incomplete outcome data (attrition bias) incidence of T2DM</p>	<p>Unclear risk</p>	<p>Quote from publication: “Of the 577 subjects with IGT who were randomized, 530 completed the study. Of the remainder, 7 people refused follow-up, 29 left Da Qing in 1988 (mostly because of the establishment of a new oil field elsewhere), and 11 died during the course of the study.”</p> <p>Comment: not reported to which group the 29 participants who left the trial were randomised</p>
<p>Incomplete outcome data (attrition bias) measures of blood glucose control</p>	<p>Unclear risk</p>	<p>Quote from publication: “Of the 577 subjects with IGT who were randomized, 530 completed the study. Of the remainder, 7 people refused follow-up, 29 left Da Qing in 1988 (mostly because</p>

Da Qing 1997 (Continued)

		<p>of the establishment of a new oil field elsewhere), and 11 died during the course of the study.”</p> <p>Comment: not reported to which group the 29 participants who left the trial were randomised</p>
Incomplete outcome data (attrition bias) non-serious adverse events	Unclear risk	<p>Quote from publication: “Of the 577 subjects with IGT who were randomized, 530 completed the study. Of the remainder, 7 people refused follow-up, 29 left Da Qing in 1988 (mostly because of the establishment of a new oil field elsewhere), and 11 died during the course of the study.”</p> <p>Comment: not reported to which group the 29 participants who left the trial were randomised</p>
Incomplete outcome data (attrition bias) serious adverse events	Unclear risk	<p>Quote from publication: “Of the 577 subjects with IGT who were randomized, 530 completed the study. Of the remainder, 7 people refused follow-up, 29 left Da Qing in 1988 (mostly because of the establishment of a new oil field elsewhere), and 11 died during the course of the study.”</p> <p>Comment: not reported to which group the 29 participants who left the trial were randomised</p>
Selective reporting (reporting bias)	High risk	<p>Comment: It is apparent from an abstract of the trial that cardiovascular outcomes were collected, but they were not reported in a format suitable for meta-analyses. One of the articles reported that HRQoL and use of health care was evaluated, but there were no data</p>
Other bias	High risk	<p>Comment: the study was cluster-randomised, and no ICC was reported. Therefore, all data in the meta-analyses are based on an assumed intra-cluster coefficient</p>

Methods	Parallel randomised controlled clinical trial, randomisation ratio 1:1
Participants	<p>Inclusion criteria: ≥ 25 years, BMI ≥ 24 kg/m² in Asians BMI ≥ 22 kg/m², FPG 95-125 mg/dl (5.3-6.9 mmol/L) and 2 hour plasma glucose after an OGTT 140-199 mg/dL (7.8-11.0 mmol/L). Because of the relative higher rate of progression from impaired glucose tolerance to diabetes in Native Americans and the small size of the population, the glucose requirement for eligibility in the Southwest American Indian Center will be fasting glucose < 126 mg/dL (7.0 mmol/L) and 2 hour plasma glucose after an OGTT 140-199 mg/dL (7.8-11.0 mmol/L)</p> <p>Exclusion criteria: T2DM, participants taking medicines known to alter glucose tolerance, ever used glucose-lowering drugs during pregnancy, illnesses that could seriously reduce their life expectancy or their ability to participate in the trial, cardiovascular disease (hospitalisation for treatment of heart disease in past 6 months; NYHA class > 2; left bundle branch block or third degree atrioventricular block; aortic stenosis; SBP > 180 mmHg or DBP > 105 mmHg); cancer requiring treatment in the past five years (unless prognosis is considered good); renal disease; gastrointestinal disease; anaemia (hematocrit $< 36.0\%$ in men or $< 33.0\%$ in women); electrolyte abnormality (serum potassium < 3.2 or > 5.5 mmol/L)</p> <p>Diagnostic criteria: impaired glucose tolerance (2 hour plasma glucose after an OGTT 140-199 mg/dl (7.8-11.0 mmol/L)) and elevated fasting glucose (FPG 95-125 mg/dl (5.3-6.9 mmol/L)) (ADA 1997).</p>
Interventions	<p>Number of study centres: 27</p> <p>Treatment before study: none</p> <p>Run-in period: 3 weeks; during the run-in period the participants had to fill out a daily diary and placebo pills according to a schedule</p> <p>Extension period: yes, an additional follow-up with a median of 5.7 years (IQR 5.5-5.8) after end of the intervention period</p>
Outcomes	<p>Composite outcome measures reported: yes (Quote from publication: ".....a composite microvascular-neuropathic outcome for diabetic retinopathy, nephropathy, or reduced light touch sensation in the feet. Secondary outcomes include the individual components of the composite primary outcome, cardiovascular disease, further development of diabetes, measures of glycaemia, insulin secretion, insulin sensitivity, cardiovascular disease risk factors, physical activity, nutrition, bodyweight, health-related quality of life, and economic assessments.")</p>
Study details	<p>Trial terminated early: yes, the trial was stopped one year earlier than originally planned due to larger intervention effect of diet and physical activity than anticipated</p>
Publication details	<p>Language of publication: English</p> <p>Funding: commercial funding (Lipha (Merck-Sante) provided medicines, and LifeScan donated materials)/non-commercial funding (the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), National Institute of Child Health and Human Development, the National Institute on Aging, the National Eye Institute, the National Heart Lung and Blood Institute, the Office of Women's Health, the National Center for Minority Health and Human Disease, the Centers for Disease Control and Prevention, and the American Diabetes Association)</p> <p>Publication status: peer-reviewed journal</p>

Stated aim of study	Quote from publication: "The principal objective of the DPP is to prevent or delay the development of NIDDM in those persons who are at high risk for its development by virtue of having impaired glucose tolerance"	
Notes	<p>Individuals who meet only one of the glucose inclusion criteria was re-screened after 6 months</p> <p>Because of the relative higher rate of progression from impaired glucose tolerance to T2DM in Native Americans and the small size of the population, the glucose requirement for eligibility in the Southwest American Indian Center differed (see above)</p> <p>The trial included initially four intervention groups. The metformin group is not included in this review. The troglitazone group was discontinued in 1998 because of potential liver toxicity</p>	
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	<p>Quote from publication: "A sequence of randomization numbers within a clinical center will be constructed of the form XXYZZZ, where XX is the clinical center number, Y is a number that indicates assignment to either the intensive lifestyle intervention or pharmacological treatment, and ZZZ is a three digit sequence number within each XXY combination. The DPP Coordinating Center will prepare the master randomization list with assignments to the three treatment groups within a clinical center using the standard urn design.</p> <p>The sequence of pharmacological randomization numbers within a clinical center with the specific pharmacological treatment assignment (i.e., metformin or placebo) will be forwarded, in confidence, to the drug distribution center for drug labelling and distribution. Pharmacological treatment assignment to the sequence of pharmacological randomization numbers will be known only by the staff of the DPP Coordinating Center and the drug distribution center."</p> <p>Comment: adequate generation of random sequence ensured</p>
Allocation concealment (selection bias)	Low risk	<p>Quote from publication: "A sequence of randomization numbers within a clinical center will be constructed of the form</p>

		<p>XXYZZZ, where XX is the clinical center number, Y is a number that indicates assignment to either the intensive lifestyle intervention or pharmacological treatment, and ZZZ is a three digit sequence number within each XXY combination. The DPP Coordinating Center will prepare the master randomization list with assignments to the three treatment groups within a clinical center using the standard urn design. The sequence of pharmacological randomization numbers within a clinical center with the specific pharmacological treatment assignment (i.e., metformin or placebo) will be forwarded, in confidence, to the drug distribution center for drug labelling and distribution. Pharmacological treatment assignment to the sequence of pharmacological randomization numbers will be known only by the staff of the DPP Coordinating Center and the drug distribution center.”</p> <p>Comment: adequate allocation concealment ensured</p>
<p>Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality</p>	<p>Low risk</p>	<p>Quote from publication: "Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical."</p> <p>Comment: no blinding but judged that the outcome is not likely to be influenced by lack of blinding, investigator-assessed outcome measurement</p>
<p>Blinding of participants and personnel (performance bias) incidence of T2DM</p>	<p>Low risk</p>	<p>Quote from publication: "Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical." and "Primary outcome data (OGTT and FPG results) measured centrally will remain masked to the investigators and to the participants until confirmed progression from IGT to diabetes"</p> <p>Comment: assessed centrally unblinded, the outcome is not likely to be influenced by lack of blinding. Participants and investigators blinded to until progression to T2DM</p>

Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	Quote from publication: "Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical." and "Primary outcome data (OGTT and FPG results) measured centrally will remain masked to the investigators and to the participants until confirmed progression from IGT to diabetes" and Plasma lipid levels and HbA1c measured centrally will remain masked to the investigators and to the participants during the study." Comment: assessed centrally unblinded, the outcome is not likely to be influenced by lack of blinding. Participants and investigators blinded to until progression to T2DM
Blinding of participants and personnel (performance bias) socioeconomic effects	Low risk	Quote from publication: "Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical." Comment: no blinding but judged that the outcome is not likely to be influenced by lack of blinding, investigator-assessed outcome measurement
Blinding of participants and personnel (performance bias) Health related quality of life	High risk	Quote from publication: "Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical." Comment: no blinding and the outcome is likely to be influenced by lack of blinding, self-reported outcome measurement
Blinding of outcome assessment (detection bias) all-cause/cardiovascular mortality	Low risk	Quote from publication: "Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical." Comment: no blinding but judged that the outcome is not likely to be influenced by lack of blinding, investigator-assessed outcome measurement
Blinding of outcome assessment (detection bias) incidence of T2DM	Low risk	Quote from publication: "Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical." and "Primary

		<p>outcome data (OGTT and FPG results) measured centrally will remain masked to the investigators and to the participants until confirmed progression from IGT to diabetes”</p> <p>Comment: assessed centrally unblinded, the outcome is not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) measures of blood glucose control	Low risk	<p>Quote from publication: “Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical.” and “Primary outcome data (OGTT and FPG results) measured centrally will remain masked to the investigators and to the participants until confirmed progression from IGT to diabetes” and “Plasma lipid levels and HbA1c measured centrally will remain masked to the investigators and to the participants during the study.”</p> <p>Comment: assessed centrally unblinded, the outcome is not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) socioeconomic effects	Low risk	<p>Quote from publication: “Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical.”</p> <p>Comment: no blinding but judged that the outcome is not likely to be influenced by lack of blinding, investigator-assessed outcome measurement</p>
Blinding of outcome assessment (detection bias) Health related quality of life	High risk	<p>Quote from publication: “Masking intensive lifestyle intervention assignment to the participants is not possible and masking the investigators is not practical.”</p> <p>Comment: no blinding and the outcome is likely to be influenced by lack of blinding, self-reported outcome measurement</p>
Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality	Low risk	<p>Quote from publication: “At the close of the study, 99.6 percent of the participants were alive, of whom 92.5 percent had attended a scheduled visit within the previous five months”</p> <p>Comment: not stated how many partici-</p>

		participants who had known vital status in each intervention group at the end of follow-up for the DPP trial. However, at inception of the number with unknown mortality status are relatively low. At inception of the DP-POS the number between the intervention groups we balanced
Incomplete outcome data (attrition bias) incidence of T2DM	Low risk	Quote from publication: “At the close of the study, 99.6 percent of the participants were alive, of whom 92.5 percent had attended a scheduled visit within the previous five months” Comment: not stated how many participants who had known vital status at the end of follow-up for the DPP trial. However, at inception of the DPPOS a relatively low and balanced number of participants in the intervention groups could not be included
Incomplete outcome data (attrition bias) measures of blood glucose control	Low risk	Comment: not stated how many participants who had known vital status at the end of follow-up for the DPP trial. However, at inception of the DPPOS a relatively low and balanced number between the intervention groups could not be included
Incomplete outcome data (attrition bias) time to progression to T2DM	Low risk	Comment: “At the close of the study, 99.6 percent of the participants were alive, of whom 92.5 percent had attended a scheduled visit within the previous five months”
Incomplete outcome data (attrition bias) socioeconomic effects	Low risk	Comment: not clearly described how many participants included in the costs analyses, but as the study have a high follow-up rate, we assume that nearly all participants are included
Incomplete outcome data (attrition bias) Health related quality of life	Low risk	Quote from publication: The current report and analyses includes 3,234 participants seen at baseline, who were randomly assigned to one of the three treatment arms investigated Comment: article reporting health related quality of life do not report the number of participants with available data at follow-up

DPP 2002 (Continued)

Selective reporting (reporting bias)	High risk	Comment: several outcome are likely to be measured and analysed, but not reported, e.g. hypoglycaemia, non-serious adverse events. outcomes published in many different publications. Many outcomes are reported incompletely so that they cannot be entered in a meta-analysis
Other bias	High risk	Comment: trial terminated early for benefit Comment: received funding from a pharmaceutical company

DPS 2001

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:1
Participants	Inclusion criteria: BMI \geq 25 kg/m ² ; IGT (2-h plasma glucose after an OGTT 140-200 mg/dL (7.8-11.0 mmol/L)) and FPG < 140 mg/dL (7.8 mmol/L) (WHO 1985), 40-65 years Exclusion criteria: diagnosis of diabetes mellitus, involvement of people with regularly vigorous physical activity, chronic disease, diseases likely to interfere with glucose metabolism (e.g. liver disease), psychological or physical disabilities deemed likely to interfere with participation in the study Diagnostic criteria: IGT (2-h plasma glucose after an OGTT 140-200 mg/dL (7.8-11.0 mmol/L)) and FPG < 140 mg/dL (7.8 mmol/L) (WHO 1985)
Interventions	Number of study centres: 5 Treatment before study: none Titration period: none
Outcomes	Composite outcome measures reported: no
Study details	Trial terminated early: yes (the trial was prematurely terminated in March 2000 by an independent end point committee, since the incidence of diabetes in the intervention group was highly significantly lower than in the control group)
Publication details	Language of publication: English Funding: commercial funding (Novo Nordisk Foundation)/non-commercial funding (Finnish Academy, Ministry of Education, Yrjö Jahnsson Foundation, and the Finnish Diabetes Research Foundation) Publication status: peer-reviewed journal
Stated aim of study	Quote from publication: "The aim of the Diabetes Prevention Study is to assess the efficacy of an intensive diet-exercise programme in preventing or delaying Type II (non-insulin-dependent) diabetes mellitus in subjects with impaired glucose tolerance, to evaluate the effects of the intervention programme on cardiovascular risk factors and to

	assess the determinants for the progression to diabetes in persons with impaired glucose tolerance.”	
Notes	<p>After the first screening OGTT, a repeat OGTT was carried out in participants with IGT and the mean value of the two 2-h glucose concentrations was used as the criterion for inclusion in the study</p> <p>The inclusion criteria were developed during the recruitment period but before the final criteria based on the two OGTTs were decided</p> <p>After randomisation, study visits were scheduled for 1-2 weeks, 5-6 weeks, 3, 4 and 6 months from the beginning of the study and thereafter every 3 months. Every 3 months, 3-d food records were completed throughout the study</p>	
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	<p>Quote from publication: “Subjects who enrolled in the study were randomly assigned to the intervention group or the control group by the study physician, with the use of a randomization list...” and “For the DPS and EDIPS-Newcastle (but not SLIM) the randomisation lists were generated and supplied by the coordinating centre in Helsinki and staff who made baseline measurements had no access to the randomisation lists.”</p> <p>Comment: adequate generation of random sequence ensured</p>
Allocation concealment (selection bias)	Low risk	<p>Quote from publication: “Subjects who enrolled in the study were randomly assigned to the intervention group or the control group by the study physician, with the use of a randomization list...” and “For the DPS and EDIPS-Newcastle (but not SLIM) the randomisation lists were generated and supplied by the coordinating centre in Helsinki and staff who made baseline measurements had no access to the randomisation lists.”</p> <p>Comment: adequate allocation concealment ensured</p>
Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality	Low risk	<p>Quote from publication: “The nurses who scheduled the study visits did not have access to the randomization list. However, the staff members involved in the intervention had to be aware of the group as-</p>

		<p>signment; thus, the study was only partly blinded. Laboratory staff did not know the subjects' group assignments, and the subjects were not informed of their plasma glucose concentrations during follow-up unless diabetes was diagnosed.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
<p>Blinding of participants and personnel (performance bias) incidence of T2DM</p>	<p>Low risk</p>	<p>Quote from publication: “The nurses who scheduled the study visits did not have access to the randomization list. However, the staff members involved in the intervention had to be aware of the group assignment; thus, the study was only partly blinded. Laboratory staff did not know the subjects' group assignments, and the subjects were not informed of their plasma glucose concentrations during follow-up unless diabetes was diagnosed.”</p> <p>“The independent end-points committee confirmed all newly diagnosed cases of diabetes”</p> <p>Comment: outcome evaluated by an independent outcome committee. Not described whether this committee was blinded. We assume that the outcome committee was blinded, however the outcome was not likely to be influenced by lack of blinding</p>
<p>Blinding of participants and personnel (performance bias) measures of blood glucose control</p>	<p>Low risk</p>	<p>Quote from publication: “The nurses who scheduled the study visits did not have access to the randomization list. However, the staff members involved in the intervention had to be aware of the group assignment; thus, the study was only partly blinded. Laboratory staff did not know the subjects' group assignments, and the subjects were not informed of their plasma glucose concentrations during follow-up unless diabetes was diagnosed.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>

Blinding of participants and personnel (performance bias) time to progression to T2DM	Low risk	<p>Quote from publication: “The nurses who scheduled the study visits did not have access to the randomization list. However, the staff members involved in the intervention had to be aware of the group assignment; thus, the study was only partly blinded. Laboratory staff did not know the subjects’ group assignments, and the subjects were not informed of their plasma glucose concentrations during follow-up unless diabetes was diagnosed.”</p> <p>“The independent end-points committee confirmed all newly diagnosed cases of diabetes”</p> <p>Comment: outcome evaluated by an independent outcome committee. Not described whether this committee was blinded. We assume that the outcome committee was blinded, however the outcome was not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) all-cause/cardiovascular mortality	Low risk	<p>Quote from publication: “The nurses who scheduled the study visits did not have access to the randomization list. However, the staff members involved in the intervention had to be aware of the group assignment; thus, the study was only partly blinded. Laboratory staff did not know the subjects’ group assignments, and the subjects were not informed of their plasma glucose concentrations during follow-up unless diabetes was diagnosed.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) incidence of T2DM	Low risk	<p>Quote from publication: “The nurses who scheduled the study visits did not have access to the randomization list. However, the staff members involved in the intervention had to be aware of the group assignment; thus, the study was only partly blinded. Laboratory staff did not know the subjects’ group assignments, and the subjects were not informed of their plasma glucose concentrations during follow-up unless diabetes was diagnosed.”</p>

		<p>“The independent end-points committee confirmed all newly diagnosed cases of diabetes”</p> <p>Comment: outcome evaluated by an independent outcome committee. Not described whether this committee was blinded. We assume that the outcome committee was blinded, and the outcome was not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) measures of blood glucose control	Low risk	<p>Quote from publication: “The nurses who scheduled the study visits did not have access to the randomization list. However, the staff members involved in the intervention had to be aware of the group assignment; thus, the study was only partly blinded. Laboratory staff did not know the subjects’ group assignments, and the subjects were not informed of their plasma glucose concentrations during follow-up unless diabetes was diagnosed.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) time to progression to T2DM	Low risk	<p>Quote from publication: “The nurses who scheduled the study visits did not have access to the randomization list. However, the staff members involved in the intervention had to be aware of the group assignment; thus, the study was only partly blinded. Laboratory staff did not know the subjects’ group assignments, and the subjects were not informed of their plasma glucose concentrations during follow-up unless diabetes was diagnosed.”</p> <p>“The independent end-points committee confirmed all newly diagnosed cases of diabetes”</p> <p>Comment: outcome evaluated by an independent outcome committee. Not described whether this committee was blinded. We assume that the outcome committee was blinded, and the outcome was not likely to be influenced by lack of blinding</p>

Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality	High risk	<p>Quote from publication: “During the post-intervention follow-up, 36 additional participants withdrew and ten died without a verified diabetes diagnosis”</p> <p>Comment: participants diagnosed with T2DM not included in the mortality analyses</p>
Incomplete outcome data (attrition bias) incidence of T2DM	Unclear risk	<p>Quote from publication: “During the study, 40 subjects (8 percent) withdrew - 23 in the intervention group and 17 in the control group. Of these subjects, 9 could not be contacted, 3 withdrew due to severe illness, 1 died, and 27 withdrew for personal reasons.” “Subjects who withdrew from the study were considered to be at risk for diabetes until their last oral glucose tolerance test, at which point data were censored.” 9 yrs publication: “The last-observation carried-forward method was applied to all measurements for those participants who developed diabetes or who were lost to follow-up”</p> <p>Quote from 9 years publication: “Altogether, 86 participants were lost to follow up without a diabetes diagnosis: 49 in the intervention group and 37 in the control group. The baseline characteristics of the dropouts were similar between the groups.”</p> <p>Comment: inappropriate method of imputation</p>
Incomplete outcome data (attrition bias) measures of blood glucose control	Unclear risk	<p>Comment: not explicitly stated how many participants were included in the analyses</p>
Incomplete outcome data (attrition bias) time to progression to T2DM	Unclear risk	<p>Quote from publication: “During the study, 40 subjects (8 percent) withdrew - 23 in the intervention group and 17 in the control group. Of these subjects, 9 could not be contacted, 3 withdrew due to severe illness, 1 died, and 27 withdrew for personal reasons.” “Subjects who withdrew from the study were considered to be at risk for diabetes until their last oral glucose tolerance test, at which point data were censored.” 9 yrs publication: “The last-observation carried-forward method was applied</p>

DPS 2001 (Continued)

		to all measurements for those participants who developed diabetes or who were lost to follow-up”. and Quote from 9 years publication: “Altogether, 86 participants were lost to follow up without a diabetes diagnosis: 49 in the intervention group and 37 in the control group. The baseline characteristics of the dropouts were similar between the groups.” Comment: inappropriate method of imputation
Selective reporting (reporting bias)	High risk	Comment: morbidity was described as being reported in design article, but no data available
Other bias	High risk	Comment: trial terminated early for benefit Comment: received funding from the Novo Nordisk Foundation

EDIPS 2009

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:1
Participants	Inclusion criteria: IGT (mean 2-h plasma glucose > 7.8 and < 11.1 mmol/L (WHO 1999) from 2 OGTTs, the 2nd conducted 1-12 weeks after the 1st); aged 40-74 years; BMI > 25 kg/m ² Exclusion criteria: previous diagnosis of T2DM according to WHO 1999 criteria; previous intensive treatment for IGT; previous participation in a programme of vigorous physical activity Diagnostic criteria: IGT (mean 2-h plasma glucose after OGTTs > 7.8 and < 11.1 mmol/L) (WHO 1999) No explicit mention of FPG measurements but FPG should be < 7.0 mmol/L according to the criteria suggested by the trial authors
Interventions	Number of study centres: 1 Run-in period: none Extension period: no
Outcomes	Composite outcome measures reported: no
Study details	Trial terminated early: no
Publication details	Language of publication: English Funding: non-commercial funding (Wellcome Trust) Publication status: peer-reviewed journal

Stated aim of study	Quote from publication: “The EDIPS in Newcastle upon Tyne, UK (EDIPS-Newcastle) was designed to contribute to the evidence for diabetes prevention by lifestyle modification in people with IGT.”	
Notes		
<i>Risk of bias</i>		
Bias	Authors’ judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote from publication: “Eligible participants (with IGT) were randomly allocated to the Intervention (I) or Control (C) group using randomisation lists, prepared independently by the EDIPS co-ordinating centre in Helsinki.” Comment: adequate generation of random sequence ensured
Allocation concealment (selection bias)	Low risk	Quote from publication: “Eligible participants (with IGT) were randomly allocated to the Intervention (I) or Control (C) group using randomisation lists, prepared independently by the EDIPS co-ordinating centre in Helsinki.” Comment: adequate allocation concealment ensured
Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality	Low risk	Quote from publication: “Blinding of participants and intervention staff was not possible. Data collection staff were blinded to the extent that this was possible given participants’ knowledge of their allocation.” Comment: investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) amputation, blindness/severe vision loss, end-stage renal disease	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) hypoglycaemia	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding

Blinding of participants and personnel (performance bias) incidence of T2DM	Low risk	Quote from publication: “Blinding of participants and intervention staff was not possible. Data collection staff were blinded to the extent that this was possible given participants’ knowledge of their allocation.” Comment: investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) non-fatal myocardial infarction/stroke, congestive heart failure	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) serious adverse events	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) time to progression to T2DM	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) all-cause/cardiovascular mortality	Low risk	Quote from publication: “Blinding of participants and intervention staff was not possible. Data collection staff were blinded to the extent that this was possible given participants’ knowledge of their allocation.” Comment: investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) incidence of T2DM	Low risk	Quote from publication: “Blinding of participants and intervention staff was not possible. Data collection staff were blinded to the extent that this was possible given participants’ knowledge of their allocation.” Comment: investigator-assessed outcome measurement. The outcome was not likely

		to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) measures of blood glucose control	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) non-fatal myocardial infarction/stroke, congestive heart failure	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality	Low risk	Comment: 2 in the control group and 4 in the intervention group had unknown mortality status; missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups; the proportion of missing outcomes was not enough to have a clinically relevant impact on the intervention effect estimate
Incomplete outcome data (attrition bias) amputation, blindness/severe vision loss, end-stage renal disease	Low risk	Comment: information provided by the trial authors. All participants were included in the analysis
Incomplete outcome data (attrition bias) hypoglycaemia	Low risk	Comment: information provided by the trial authors. All participants were included in the analysis
Incomplete outcome data (attrition bias) incidence of T2DM	Low risk	Quote from publication: "If participants who left the trial and were later reported to have developed T2D by their physician were included in the analysis as having developed diabetes (rather than having left) , then the number of cases of diabetes becomes 20 (I = 7, C = 13) and the relative risk of diabetes incidence becomes 0.54 (95% CI:0.2 to 1.2)." Comment: the investigators performed analyses including all participants and the participants who left the trial. The statistical significance of the effect estimate did not differ
Incomplete outcome data (attrition bias) measures of blood glucose control	Unclear risk	Comment: information provided by the trial authors. Unknown reason for missingness and how missing data were handled

EDIPS 2009 (Continued)

Incomplete outcome data (attrition bias) non-fatal myocardial infarction/stroke, congestive heart failure	Low risk	Comment: information provided by the trial authors. Investigator-assessed outcome measurement. The outcome was not likely to be influenced by lack of blinding
Incomplete outcome data (attrition bias) serious adverse events	Low risk	Comment: information provided by the trial authors. All randomised participants were included in the analysis
Incomplete outcome data (attrition bias) time to progression to T2DM	Unclear risk	Comment: information provided by the trial authors. Unknown reason for missingness and how missing data were handled
Selective reporting (reporting bias)	High risk	Comment: more outcomes of relevance to this review defined but not published (e.g. glycaemic measures). However, these data were provided by the investigators on request, except for HRQoL, which was listed as an outcome, but no additional data were provided
Other bias	Low risk	Comment: no other sources of bias identified

Hellgren 2016

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:1:1
Participants	Inclusion criteria: 35-75 years; IGT and/or IFG Exclusion criteria: T2DM Diagnostic criteria: IFG was defined as FPG > 6.0 < 7.0 mmol/L with a 2-h glucose < 8.9 mmol/L, while IGT was defined as 2-h glucose 8.8 mmol/L and < 12.2 mmol/L, and an FPG < 7.0 mmol/L
Interventions	Number of study centres: 1 Run-in period: none Extension period: no
Outcomes	Composite outcome measures reported: no
Study details	Trial terminated early: no
Publication details	Language of publication: English Funding: non-commercial funding (Swedish Research Council) Publication status: peer-reviewed journal

Stated aim of study	Quote from publication: “We hypothesised that the expected increase in insulin resistance over three years’ time in individuals with impaired glucose tolerance (IGT) and/or impaired fasting glucose could be attenuated by an intervention with focus on physical activity in ordinary primary care”
Notes	Data from the two intervention groups were initially analysed separately. As the outcomes proved to be essentially the same in both groups, the two groups were then analysed together and thereafter designated as the combined intervention group

Risk of bias

Bias	Authors’ judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote from publication: “All eligible participants were randomised to one of two different interventions, or to ‘care as usual’, using a specially designed computer system.” Comment: adequate generation of random sequence ensured
Allocation concealment (selection bias)	Low risk	Quote from publication: “All eligible participants were randomised to one of two different interventions, or to ‘care as usual’, using a specially designed computer system.” Comment: adequate generation of allocation concealment ensured
Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) amputation, blindness/severe vision loss, end-stage renal disease	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) hypoglycaemia	Unclear risk	Comment: could be investigator-assessed or self-reported outcome measure depending on the severity. No blinding described
Blinding of participants and personnel (performance bias) incidence of T2DM	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding

Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) non-fatal myocardial infarction/stroke, congestive heart failure	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) serious adverse events	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) Health related quality of life	High risk	Comment: self-reported outcome measure. No blinding. The outcome was likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) all-cause/cardiovascular mortality	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) amputation, blindness/severe vision loss, end-stage renal disease	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) hypoglycaemia	Unclear risk	Comment: could be investigator-assessed or self-reported outcome measure depending on the severity. No blinding described
Blinding of outcome assessment (detection bias) incidence of T2DM	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) measures of blood glucose control	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) non-fatal myocardial infarction/stroke, congestive heart failure	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding

Blinding of outcome assessment (detection bias) serious adverse events	Low risk	Comment: investigator-assessed outcome measure. No blinding described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) Health related quality of life	High risk	Comment: self-reported outcome measure. No blinding. The outcome was likely to be influenced by lack of blinding
Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality	Low risk	Comment: reply from the investigators that mortality status was known on all randomised participants
Incomplete outcome data (attrition bias) incidence of T2DM	Low risk	Quote from publication: “Four people died during the first year from reasons not associated with the study, and 10 of the participants developed Type 2 diabetes and refrained from the final examination. Another 13 participants dropped out of the study for various reasons (e.g. worsening general health, difficulties attending the group sessions and other social reasons). Most of the dropouts were in the intervention group (N = 5 in the IIG and N = 6 in the BIG).” Comment: a total of 13 participants dropped out, but were contacted and asked at the end of the trial and asked if they had developed T2DM. 11 of these were from the intervention group; 2 of these from the standard group. The reason for dropout was not explained. The proportion of missing outcomes was enough to induce clinically relevant bias in intervention effect estimate
Incomplete outcome data (attrition bias) measures of blood glucose control	Unclear risk	Comment: data provided by the investigators. Only about 70% of the randomised participants were included in the analyses. Unclear how missing data were handled
Incomplete outcome data (attrition bias) non-fatal myocardial infarction/stroke, congestive heart failure	Unclear risk	Comment: data provided by the investigators. Only about 80% were included in the analyses. Not clear how missing data were handled
Incomplete outcome data (attrition bias) serious adverse events	Unclear risk	Comment: information on number provided by the trial authors. Participants lost to follow-up not included in the analysis

Hellgren 2016 (Continued)

Incomplete outcome data (attrition bias) Health related quality of life	High risk	Comment: data provided by the investigators. Only about 60% of the randomised participants were included in the analyses. Not clear how missing data were handled
Selective reporting (reporting bias)	Low risk	Comment: trial protocol provided by the investigator. The trial assessed several outcomes of interest to the review but these were either not reported in publications or reported in a format that made them unsuitable for meta-analysis. However, the investigators provided the additional information
Other bias	Low risk	Comment: no other sources of bias identified

HELP PD 2011

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:1
Participants	<p>Inclusion criteria: able to read/understand English at or above a level sufficient to comprehend recruitment and intervention materials; BMI ≥ 25 kg/m² but < 40 kg/m²; fasting blood glucose 95-125 mg/dL (inclusive); ≥ 21 years</p> <p>Exclusion criteria: currently involved in a supervised programme for weight loss; history of DM, or newly diagnosed DM at screening; history of CVD occurring within the past 6 months, including myocardial infarction, angina, coronary revascularisation, stroke, transient ischaemic attack, carotid revascularisation, peripheral arterial disease, and congestive heart failure; uncontrolled high blood pressure ($> 160/100$ mmHg); pregnancy, breast feeding, or planning pregnancy within 2 years; other chronic disease likely to limit lifespan to < 2-3 years, including any cancer requiring treatment in past 5 years except non-melanoma skin cancer; chronic use of medicine known to significantly affect glucose metabolism, e.g. corticosteroids; conditions/criteria likely to interfere with participation and acceptance of randomised assignment, including the following: inability/unwillingness to give informed consent, another household member already randomised to HELP PD, major psychiatric or cognitive problems (schizophrenia, dementia, self-reported active illegal substance or alcohol abuse), and participation in another research study that would interfere with HELP PD</p> <p>Diagnostic criteria: fasting blood glucose 95-125 mg/dL (5.3-6.9 mmol/L) (inclusive)</p>
Interventions	<p>Number of study centres: 1</p> <p>Run-in period: none</p> <p>Extension period: according to clinicaltrial.com then an extension period is planned</p>
Outcomes	Composite outcome measures reported: no
Study details	Trial terminated early: no

Publication details	<p>Language of publication: English</p> <p>Funding: non-commercial funding (National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK))</p> <p>Publication status: peer-reviewed journal</p>
Stated aim of study	<p>Quote from publication: “To examine the impact of a 24-month, community-based diabetes prevention program on fasting blood glucose, insulin, insulin resistance as well as body weight, waist circumference, and BMI in the second year of follow-up”</p>
Notes	<p>Some of the publications were supported by Joslin Diabetes Center and Novo Nordisk. According to ClinicalTrials.gov an extended follow-up period up to 72 months after randomisation was planned</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	<p>Quote from publication: “Eligible participants were randomly assigned, if equal probability, to either the lifestyle intervention or the enhanced usual care arm using a web-based data management system that verifies eligibility”</p> <p>Comment: adequate generation of random sequence ensured</p>
Allocation concealment (selection bias)	Low risk	<p>Quote from publication: “Eligible participants were randomly assigned, if equal probability, to either the lifestyle intervention or the enhanced usual care arm using a web-based data management system that verifies eligibility”</p> <p>Comment: adequate allocation concealment ensured</p>
Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality	Unclear risk	<p>Quote from publication: “Outcomes are masked and are collected every 6 months” “Although neither the participants nor interventionists were masked to treatment assignment, the primary outcome, fasting blood glucose, was chosen to be highly objective.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of participants and personnel (performance bias)	Low risk	<p>Quote from publication: “Outcomes are masked and are collected every 6 months”</p>

incidence of T2DM		<p>“Although neither the participants nor interventionists were masked to treatment assignment, the primary outcome, fasting blood glucose, was chosen to be highly objective.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	<p>Quote from publication: “Outcomes are masked and are collected every 6 months”</p> <p>“Although neither the participants nor interventionists were masked to treatment assignment, the primary outcome, fasting blood glucose, was chosen to be highly objective.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of participants and personnel (performance bias) socioeconomic effects	Low risk	<p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) all-cause/cardiovascular mortality	Low risk	<p>Quote from publication: “Outcomes are masked and are collected every 6 months”</p> <p>“Although neither the participants nor interventionists were masked to treatment assignment, the primary outcome, fasting blood glucose, was chosen to be highly objective.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) incidence of T2DM	Low risk	<p>Quote from publication: “Outcomes are masked and are collected every 6 months”</p> <p>“Although neither the participants nor interventionists were masked to treatment assignment, the primary outcome, fasting blood glucose, was chosen to be highly objective.”</p> <p>Comment: investigator assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) measures of blood glucose control	Low risk	<p>Quote from publication: “Outcomes are masked and are collected every 6 months”</p> <p>“Although neither the participants nor in-</p>

		<p>terventionists were masked to treatment assignment, the primary outcome, fasting blood glucose, was chosen to be highly objective.”</p> <p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Blinding of outcome assessment (detection bias) socioeconomic effects	Low risk	<p>Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding</p>
Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality	Low risk	<p>Quote from publication: “An intention-to-treat approach was used and included all postrandomized values according to the group they were assigned”</p> <p>Comment: 1% of the randomised participants refused or withdrew by 24 months’ assessment in the intervention group; 3% of the randomised participants in the control group refused or withdrew by 24 months’ follow-up</p>
Incomplete outcome data (attrition bias) incidence of T2DM	Unclear risk	<p>Quote from publication: “An intention-to-treat approach was used and included all postrandomized values according to the group they were assigned”</p> <p>Comment: 84% of the randomised participants completed 24-month assessment in the intervention group; 89% of the randomised participants in the control group completed 24 months’ follow-up. Insufficient information to assess whether missing data were likely to induce bias</p>
Incomplete outcome data (attrition bias) measures of blood glucose control	Unclear risk	<p>Quote from publication: “An intention-to-treat approach was used and included all postrandomized values according to the group they were assigned”</p> <p>Comment: 84% of the randomised participants completed 24-month assessment in the intervention group; 89% of the randomised participants in the control group completed 24 months’ follow-up. Insufficient information to assess whether missing data were likely to induce bias</p>

Incomplete outcome data (attrition bias) time to progression to T2DM	Unclear risk	<p>Quote from publication: “The distribution of times until the development of DM and the metabolic syndrome (measured from the date of randomization to the date of the clinical visit or report triggering the diagnosis) will be described using Kaplan-Meier plots ..., with censoring taken to occur at the time of the last contact with participants”</p> <p>Comment: data were censored at the last time of contact with the participants, and not the time of diagnosis which could exaggerate a potential intervention effect</p>
Incomplete outcome data (attrition bias) socioeconomic effects	Unclear risk	<p>Quote from publication: “An intention-to-treat approach was used and included all postrandomized values according to the group they were assigned”</p> <p>Comment: 84% of the randomised participants completed 24-month assessment in the intervention group; 89% of the randomised participants in the control group completed 24 months’ follow-up. Insufficient information to assess whether missing data were likely to induce bias</p>
Selective reporting (reporting bias)	High risk	<p>Comment: several outcomes of interest for this review were measured but not reported (see table Appendix 7)</p>
Other bias	Unclear risk	<p>Comment: some of the publications were supported by Novo Nordisk. According to ClinicalTrials.gov an extended follow-up period to 72 months after randomisation was planned. Data from the extension period are still not available</p>

IDPP 2006

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:1
Participants	<p>Inclusion criteria: IGT (mean 2-h plasma glucose after OGTT 140-199 mg/dL (7.8-11.0 mmol/L) and FPG < 126 mg/dL (7.0 mmol/L)) (WHO 1999); no major illness; 35-55 years</p> <p>Exclusion criteria: diagnosis of DM during recruitment; pregnancy</p> <p>Diagnostic criteria: IGT (WHO 1999)</p>

Interventions	Number of study centres: - Treatment before study: none Titration period: none
Outcomes	Composite outcome measures reported: yes (CVD)
Study details	Trial terminated early: yes; Quote from publication: "After a median follow-up period of 30 months, because there were significant differences in the outcome measure between the control and intervention groups, the committee recommended the termination of the study in December 2004"
Publication details	Language of publication: English Funding: commercial (M/S US Vitamins) Publication status: peer-reviewed journal
Stated aim of study	Quote from publication: "In a prospective community-based study, we tested whether the progression to diabetes could be influenced by interventions in native Asian Indians with IGT who were younger, leaner and more insulin resistant than the above populations"
Notes	Two more intervention groups existed that were not included in this review; 1) metformin and 2) diet plus physical activity combined with metformin

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote from publication: "A randomised, controlled clinical trial was performed in subjects who were....." Comment: insufficient information about the sequence generation process
Allocation concealment (selection bias)	Unclear risk	Comment: no information
Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality	Low risk	Quote from publication: "Masking: Open Label" and "However, the principal investigators were blinded to the outcome until they were asked to close the study by the international data monitoring committee." Comment: outcome evaluated by an independent outcome committee. No blinding
Blinding of participants and personnel (performance bias) hypoglycaemia	High risk	Quote from publication: "Masking: Open Label" and "However, the principal investigators were blinded to the outcome until they were asked to close the study by

		the international data monitoring committee.“ Comment: self-reported and investigator-assessed outcome measure. No blinding. The outcome could have been influenced by lack of blinding. No hypoglycaemic events in the groups of interest for this review were reported
Blinding of participants and personnel (performance bias) incidence of T2DM	Low risk	Quote from publication: "Masking: Open Label" "However, the principal investigators were blinded to the outcome until they were asked to close the study by the international data monitoring committee." Comment: outcome evaluated by an independent outcome committee and investigator-assessed outcome measure
Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	Quote from publication: "Masking: Open Label" and "However, the principal investigators were blinded to the outcome until they were asked to close the study by the international data monitoring committee." Comment: investigator-assessed outcome measure, unclear if this outcome also was assessed by the blinded independent outcome committee. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) all-cause/cardiovascular mortality	Low risk	Quote from publication: "However, the principal investigators were blinded to the outcome until they were asked to close the study by the international data monitoring committee." Comment: outcome evaluated by an independent outcome committee
Blinding of outcome assessment (detection bias) hypoglycaemia	High risk	Comment: self-reported and investigator-assessed outcome measure. No blinding. The outcome could have been influenced by lack of blinding. No hypoglycaemic events in the groups of interest for this review were reported
Blinding of outcome assessment (detection bias) incidence of T2DM	Low risk	Quote from publication: "However, the principal investigators were blinded to the outcome until they were asked to close the

		<p>study by the international data monitoring committee.”</p> <p>Comment: outcome evaluated by an independent outcome committee and investigator-assessed outcome measure</p>
<p>Blinding of outcome assessment (detection bias) measures of blood glucose control</p>	Low risk	<p>Quote from publication: “However, the principal investigators were blinded to the outcome until they were asked to close the study by the international data monitoring committee.”</p> <p>Comment: investigator-assessed outcome measure, unclear if this outcome also was assessed by the blinded independent outcome committee. The outcome was not likely to be influenced by lack of blinding</p>
<p>Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality</p>	Unclear risk	<p>Comment: unknown whether mortality status known for participants lost to follow-up. 7 participants in the DPPA group and 2 participants in the control group were lost to follow-up; 5 participants in the DPPA group were mentioned as not willing. However, the proportion of missing outcomes compared with observed event risk may have had a clinically relevant impact on the intervention effect estimate</p>
<p>Incomplete outcome data (attrition bias) hypoglycaemia</p>	Unclear risk	<p>Comment: 7 participants in the DPPA group and 2 participants in the control group were lost to follow-up; 5 participants in the DPPA group were mentioned as not willing. The proportion of missing outcomes compared with observed event risk was not enough to have a clinically relevant impact on the intervention effect estimate</p>
<p>Incomplete outcome data (attrition bias) incidence of T2DM</p>	Unclear risk	<p>Comment: 7 participants in the DPPA group and 2 participants in the control group were lost to follow-up; 5 participants in the DPPA group were mentioned as not willing. The proportion of missing outcomes compared with observed event risk was not enough to have had a clinically relevant impact on the intervention effect estimate</p>
<p>Incomplete outcome data (attrition bias) measures of blood glucose control</p>	Unclear risk	<p>Comment: only 79% of the participants randomised to the intervention group and</p>

IDPP 2006 (Continued)

		91% of the participants randomised to the control group were included in the analysis of glycaemic measures. Insufficient information to assess whether missing data in combination with the method used to handle missing data were likely to induce bias
Selective reporting (reporting bias)	High risk	Quote from publication: “An internal safety committee monitored the adverse events and safety of study protocol. The data and final outcome measures were monitored by the international monitoring committee who had looked at the results three times, i.e. when 500 subjects had completed the follow-up assessments at 12, 24 and 30 months. The principal investigators were blinded to the interim results.” Comment: several outcomes with relevance for this review not reported or only reported in a format that made them unsuitable for meta-analyses, e.g. adverse events
Other bias	High risk	Comment: trial terminated early for benefit Comment: role of funding source not described

JDPP 2013

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:1
Participants	Inclusion criteria: aged 30-60 years; IGT based on WHO 1999 criteria (mean 2-ho plasma glucose after OGTT 7.8-11.0 mmol/L and FPG < 7.0 mmol/L) Exclusion criteria: previous diagnosis of DM other than gestational diabetes; a history of gastrectomy; physical conditions such as ischaemic heart disease, heart failure, exercise-induced asthma and orthopedic problems where physical activity was not allowed by a doctor; liver and kidney diseases; autoimmune diseases; habit of heavy alcohol drinking, already having vigorous physical activity Diagnostic criteria: several diagnostic criteria for impaired glucose tolerance, therein the WHO 1998
Interventions	Number of study centres: 32 Treatment before study: - Titration period: -
Outcomes	Composite outcome measures reported: no
Study details	Trial terminated early: no

Publication details	<p>Language of publication: English and Japanese Funding: non-commercial funding (Ministry of Health, Labour and Welfare, Japan) Publication status: peer-reviewed journal</p>	
Stated aim of study	<p>Quote from publication: “A randomized control trial was performed to test whether a lifestyle intervention program, carried out in a primary healthcare setting using existing resources, can reduce the incidence of type 2 diabetes in Japanese with impaired glucose tolerance (IGT).”</p>	
Notes	<p>This trial was excluded from the original Cochrane Review as it was classified as not randomised The sample size calculation of the trial was based on an anticipated incidence of T2DM during 6 years of follow-up. It was described that six years follow-up was planned, but only three years follow-up was reported Quote from publication: “Participants with IGT, aged 30-60 years, were recruited through health checkups conducted at each collaborative center. The recruitment started in March 1999 and was completed in December 2002. A two-step strategy was adopted for identifying participants with IGT as described previously. The definition of IGT using 75 g oral glucose tolerance test (OGTT) was based on the WHO’s criteria”</p>	
Risk of bias		
Bias	Authors’ judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	<p>Quote from publication: “Participants were randomly allocated (allocation ratio 1:1) to the ILG or the UCG, using a computer-generated randomization. The Taves method of minimization¹³ was used to ensure that the groups were balanced for public health centers, gender, age groups” Comment: adequate generation of random sequence ensured</p>
Allocation concealment (selection bias)	Low risk	<p>Quote from publication: “Participants were randomly allocated (allocation ratio 1:1) to the ILG or the UCG, using a computer-generated randomization. The Taves method of minimization¹³ was used to ensure that the groups were balanced for public health centers, gender, age groups” Comment: adequate allocation concealment ensured</p>
Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality	Low risk	<p>Quote from publication: “The result of the randomization was unmasked to the participants, those administering the interventions, and those assessing the data”</p>

		Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) incidence of T2DM	Low risk	Quote from publication: “The result of the randomization was unmasked to the participants, those administering the interventions, and those assessing the data” Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	Quote from publication: “The result of the randomization was unmasked to the participants, those administering the interventions, and those assessing the data” Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding
Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality	Unclear risk	Quote from publication: “We randomly assigned the 304 subjects with IGT to two groups and analyzed the data for 296 individuals (150 in the control group and 146 in the intervention group) (Figure 1). A total of 83 subjects (28%) withdrew from the study before the 3-year mark (40 in the control group and 43 in the intervention group). The withdrawals were due to personal reasons (moving etc) in 18 cases, medical reasons in 5, and loss of contact in 40. Twenty subjects were not able to continue the study for reasons related to the collaborative centers themselves, such as the closure of a center. The rate of withdrawal was higher among men than women (36.9% vs. 19.0%, $p < 0.01$).” Comment: reason for loss to follow-up in intervention group: personal reasons (N = 11); medical reasons (N = 3); loss of contact (N = 21); closure of centres (N = 8); reason for loss to follow-up in the comparator group: personal reasons (N = 7); medical reasons (N = 2); loss of contact (N = 19); closure of centres (N = 12) A relatively large number of participants did not complete the trial. However, the number and reasons for missingness were balanced between the intervention groups

<p>Incomplete outcome data (attrition bias) incidence of T2DM</p>	<p>Unclear risk</p>	<p>Quote from publication: “We randomly assigned the 304 subjects with IGT to two groups and analyzed the data for 296 individuals (150 in the control group and 146 in the intervention group) (Figure 1). However, the number and reasons for missingness were balanced between the intervention groups</p>
Selective reporting (reporting bias)	High risk	Comment: it is clear from publication that adverse events were collected and HbA1c analysed, but data could not be entered in the meta-analysis
Other bias	Low risk	Comment: no other sources of bias identified

Kosaka 2005

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:4
Participants	<p>Inclusion criteria: impaired glucose tolerance (FPG < 140 mg/dL (7.8 mmol/L) and a 2-h plasma glucose value between 160-239 mg/dL (8.9-13.3 mmol/L) on 100 g OGTTs; which roughly corresponds to 140-199 mg/dL on 75 g OGTT); men</p> <p>Exclusion criteria: known DM, diagnosed or suspected malignant neoplasm, diagnosed or suspected disease of the liver, pancreas, endocrine organs, or kidney; ischaemic heart disease or cerebrovascular disease or a history of such disease</p> <p>Diagnostic criteria: IGT roughly according to the WHO 1980 criteria (WHO 1980)</p>
Interventions	<p>Number of study centres: -</p> <p>Treatment before study: -</p> <p>Titration period: none</p>
Outcomes	Composite outcome measures reported: no
Study details	Trial terminated early: no
Publication details	<p>Language of publication: English</p> <p>Funding: NR</p> <p>Publication status: peer-reviewed journal</p>
Stated aim of study	Quote from publication: "In this paper, we report that the development of diabetes can be significantly prevented by intervention in lifestyle designed to achieve and maintain the ideal body weight of each individual during an observation period of 4 years in subjects with IGT."

Notes	Only men were included as trial authors expected a higher dropout rate among women	
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote from publication: "One of every five subjects was randomly selected for allocation the intensive intervention group, and the others were assigned to the standard intervention (control) group." Comment: insufficient information about the sequence generation process
Allocation concealment (selection bias)	Unclear risk	Comment: no information
Blinding of participants and personnel (performance bias) incidence of T2DM	Low risk	Comment: investigator-assessed outcome measure. No blinding of participants described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) incidence of T2DM	Unclear risk	Comment: investigator-assessed outcome measure. No blinding of outcome assessors described. The outcome was not likely to be influenced by lack of blinding
Incomplete outcome data (attrition bias) incidence of T2DM	High risk	Comment: 88.8% of the originally randomised participants in the intervention group and 86.2% of the originally randomised participants in the control group had complete data for the diabetes outcome. Method of handling missing data as well as explanation of dropouts was not stated in the paper
Selective reporting (reporting bias)	High risk	Comment: no trial protocol available. Glycaemic measures analysed but no data reported
Other bias	Unclear risk	Comment: no funding source provided

Oldroyd 2005

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:1	
Participants	<p>Inclusion criteria: IGT (2-h plasma glucose after an OGTT 140-200 mg/dL (7.8-11.0 mmol/L)) (WHO 1985); 24-75 years; European origin</p> <p>Exclusion criteria: pregnant individuals, on therapeutic diets or whose medical condition prevented them from undertaking moderate physical activity</p> <p>Diagnostic criteria: IGT (2-h plasma glucose after an OGTT 140-200 mg/dL (7.8-11.0 mmol/L)) (WHO 1985)</p>

PODOSA 2014

Methods	Cluster-randomised, controlled, clinical trial, randomisation ratio 1:1
Participants	<p>Inclusion criteria: Indian and Pakistani origin; normal place of residence is in Greater Glasgow & Clyde or Lothian Health Board areas; given informed consent; IGT on OGTT at least once or IFG; age \geq 35 years; waist size of > 90 cm (men) or > 80 cm (women); no confirmed medical history of diabetes (other than gestational diabetes)</p> <p>Exclusion criteria: unwilling to give consent to co-operate; T2DM on the OGTT during the screening phase of the study; other disease where adherence to the intervention is contraindicated or improbable e.g. terminal illness or psychological or physical illnesses; alcohol dependency; planned or actual pregnancy; use of prescribed drugs that affect the primary outcome; expectation, reported by participants or the general practitioner, that the person will be emigrating or dying before the conclusion of the trial; failure to make a commitment to stay in the study until, at least, the 3-year follow-up examination</p> <p>Diagnostic criteria: IGT (mean 2-h post prandial plasma glucose 7.8-11.0 mmol/L and FPG < 7.0 mmol/L or IFG (FPG 6.1-6.9 mmol/L)) (WHO 1999)</p>
Interventions	<p>Number of study centres: -</p> <p>Treatment before study: none</p> <p>Titration period: none</p>
Outcomes	Composite outcome measures reported: no
Study details	Trial terminated early: no
Publication details	<p>Language of publication: English</p> <p>Funding: non-commercial (National Prevention Research Initiative)</p> <p>Publication status: peer-reviewed journal</p>
Stated aim of study	Quote from publication: "To evaluate whether a 3-year family based programme combining weight loss and physical activity can reduce the incidence of type 2 diabetes in South Asians with impaired glucose tolerance."
Notes	Cluster-randomised trial: family clusters (78 families with 85 participants were allocated to the intervention group and 78 families with 86 participants were allocated to the control group. Adult relatives (known as family volunteers) to support participants in behaviour change. Eligible family volunteers were aged \geq 18 years and reported interact-

	ing with participants at least weekly. 53% of the families in the intervention group had family volunteers and 56% of the families in the control group. Investigators confirmed data and provided information on which outcomes were not assessed in the trial	
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote from publication: "Families were randomised (using a random number generator program, with permuted blocks of random size, stratified by location [Edinburgh or Glasgow], ethnic group [Indian or Pakistani], and number of participants in the family [one vs more than one]) to intervention or control. Participants in the same family were not randomised separately" Comment: adequate generation of random sequence ensured
Allocation concealment (selection bias)	Low risk	Quote from publication: "Families were randomised (using a random number generator program, with permuted blocks of random size, stratified by location [Edinburgh or Glasgow], ethnic group [Indian or Pakistani], and number of participants in the family [one vs more than one]) to intervention or control. Participants in the same family were not randomised separately" Comment: adequate allocation concealment ensured
Blinding of participants and personnel (performance bias) incidence of T2DM	Low risk	Quote from publication: "We did this non-blinded trial in two National Health Service (NHS) regions in Scotland (UK)." and "There was no masking of group status except for the 3-year measure of weight, waist size, and hip size by independent research nurses" Comment: investigator-assessed outcome measure. No blinding of participants or investigators. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	Quote from publication: "We did this non-blinded trial in two National Health Service (NHS) regions in Scotland (UK)." and "There was no masking of group status except for the 3-year measure of weight,

		<p>waist size, and hip size by independent research nurses”</p> <p>Comment: investigator-assessed outcome measure. No blinding of participants or investigators. The outcome was not likely to be influenced by lack of blinding</p>
<p>Blinding of participants and personnel (performance bias) non-serious adverse events</p>	<p>High risk</p>	<p>Quote from publication: “We did this non-blinded trial in two National Health Service (NHS) regions in Scotland (UK).” and “There was no masking of group status except for the 3-year measure of weight, waist size, and hip size by independent research nurses”</p> <p>Comment: self-reported and investigator-assessed outcome measure. 		search nurses” Comment: investigator-assessed outcome measure. No blinding. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) non-serious adverse events	High risk	Quote from publication: “We did this non-blinded trial in two National Health Service (NHS) regions in Scotland (UK).” and “There was no masking of group status except for the 3-year measure of weight, waist size, and hip size by independent research nurses” Comment: investigator-assessed outcome measure. No blinding. The outcome could have been influenced by lack of blinding
Blinding of outcome assessment (detection bias) socioeconomic effects	Low risk	Quote from publication: “We did this non-blinded trial in two National Health Service (NHS) regions in Scotland (UK).” and “There was no masking of group status except for the 3-year measure of weight, waist size, and hip size by independent research nurses” Comment: investigator-assessed outcome measure. The outcome was not likely to be influenced by lack of blinding
Incomplete outcome data (attrition bias) incidence of T2DM	Low risk	Quote from publication: “Analyses were by modified intention to treat, excluding participants who died or were lost to follow-up” Comment: 95% of the participants in each intervention group had complete glycaemic data after 3 years of intervention. Missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups. The proportion of missing outcomes was not enough to have had a clinically relevant impact on the intervention effect estimate
Incomplete outcome data (attrition bias) measures of blood glucose control	Low risk	Quote from publication: “Analyses were by modified intention to treat, excluding participants who died or were lost to follow-up” Comment: 95% of the participants in each intervention group had complete glycaemic data after 3 years of intervention.

		Missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups. The proportion of missing outcomes was not enough to have had a clinically relevant impact on the intervention effect estimate
Incomplete outcome data (attrition bias) non-serious adverse events	Low risk	Quote from publication: “Analyses were by modified intention to treat, excluding participants who died or were lost to follow-up” Comment: missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups. The proportion of missing outcomes was not enough to have had a clinically relevant impact on the intervention effect estimate
Incomplete outcome data (attrition bias) socioeconomic effects	Low risk	Quote from publication: “Analyses were by modified intention to treat, excluding participants who died or were lost to follow-up” Comment: missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups. The proportion of missing outcomes was not enough to have had a clinically relevant impact on the intervention effect estimate
Selective reporting (reporting bias)	Unclear risk	Quote from publication: “The primary outcome of the trial was, therefore, altered on June 29, 2009, to change in weight at 3 years to ensure sufficient statistical power, in agreement with the Trial Steering Committee, Data Monitoring and Ethics Committee, and funders. Weight change at 3 years was included in the original protocol as a secondary outcome.” Comment: the investigator replied that none of the outcomes that had relevance to this review were unpublished. Outcomes that were not published had not been collected (e.g. mortality)
Other bias	Low risk	Comment: no other sources of bias identified. The ICC was negative

SLIM 2003

Methods	Parallel, randomised, controlled, clinical trial, randomisation ratio 1:1	
Participants	<p>Inclusion criteria: mean 2-h blood glucose ≥ 7.8 and ≤ 12.5 mmol/L; mean fasting blood glucose ≤ 7.8 mmol/L; white; age 40-70 years</p> <p>Exclusion criteria: known DM; mean 2-hour blood glucose > 12.5 mmol/L; mean fasting blood glucose > 7.8 mmol/L; any chronic illness that made 5 years' survival improbable, or that interfered with glucose tolerance, or that made participation in a lifestyle-intervention impossible; medication known to interfere with glucose tolerance; participation in a regular vigorous physical activity and/or diet programme</p> <p>Diagnostic criteria: impaired glucose tolerance (mean 2-h blood glucose ≥ 7.8 and ≤ 12.5 mmol/L; mean fasting blood glucose ≤ 7.8 mmol/L)</p>	
Interventions	<p>Number of study centres: -</p> <p>Treatment before study: none</p> <p>Titration period: none</p>	
Outcomes	Composite outcome measures reported: no	
Study details	Trial terminated early: no	
Publication details	<p>Language of publication: English</p> <p>Funding: non-commercial funding (Netherlands Organisation for Scientific Research (ZonMW: 940-35-034) and the Dutch Diabetes Research Foundation (DFN: 98.901)</p> <p>Publication status: peer-reviewed journal</p>	
Stated aim of study	<p>Quote from publication: "The high prevalence of disturbances in glucose homeostasis observed in the preliminary screening underscore the importance of early (lifestyle) interventions in those at risk for developing diabetes. SLIM will address this topic in the Dutch population."</p>	
Notes	<p>Glycemic measures in the inclusion criteria are expressed as venous blood glucose and not as plasma glucose</p> <p>Originally, the trial follow-up was planned to have a duration of the intervention for 3 years, but was extended to 6 years during the study. In 2002, a 2nd screening was performed and additional 33 participants were included</p>	
<i>Risk of bias</i>		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	<p>Quote from publication: "Randomisation was carried out with stratification for sex and mean 2 h-plasma glucose concentration."</p> <p>Comment: insufficient information about the sequence generation process</p>
Allocation concealment (selection bias)	Unclear risk	Comment: no information

Blinding of participants and personnel (performance bias) all-cause mortality/cardiovascular mortality	Low risk	Comment: investigator-assessed outcome measure. No blinding of participants or investigators described. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) incidence of T2DM	Low risk	Comment: investigator-assessed outcome measure. No blinding of participants or investigators described. The outcome was not likely to be influenced by lack of blinding
Blinding of participants and personnel (performance bias) measures of blood glucose control	Low risk	Comment: investigator-assessed outcome measure. No blinding of participants or investigators described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) all-cause/cardiovascular mortality	Low risk	Comment: investigator-assessed outcome measure. No blinding of investigators described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) incidence of T2DM	Low risk	Comment: investigator-assessed outcome measure. No blinding of investigators described. The outcome was not likely to be influenced by lack of blinding
Blinding of outcome assessment (detection bias) measures of blood glucose control	Low risk	Comment: investigator-assessed outcome measure. No blinding of investigators described. The outcome was not likely to be influenced by lack of blinding
Incomplete outcome data (attrition bias) all-cause/cardiovascular mortality	Low risk	Comment: mortality status was unknown in 1 person in each intervention group (Figure 1; Roumen et al. European Journal of Clinical Nutrition (2011)). This proportion of missing outcomes was not enough to have had a clinically relevant impact on the intervention effect estimate
Incomplete outcome data (attrition bias) incidence of T2DM	High risk	Comment: 47% in the intervention group and 48% in the control group completed 6 years' follow-up. Not described how the missing data for this variable was handled. The proportion of missing data was large enough to have had a clinically relevant impact on the intervention effect estimate. Besides, it was clear from the publication that the participants who dropped out were more obese, had higher glucose values on a

		2-h OGTT and had lower economic status at baseline
Incomplete outcome data (attrition bias) measures of blood glucose control	High risk	Quote from publication: “Changes over time between groups were assessed using mixed model analysis on intention-to-treat, which included all available observations, including those from later dropouts.” Comment: 77% of the participants initially randomised to the intervention group and 79% in the control group were included in the analyses of glycaemic measures. This proportion of missing data was large enough to have had a clinically relevant impact on the intervention effect estimate. Besides, it was clear from the publication that the participants who dropped out at baseline were more obese, had higher glucose values on a 2-h OGTT and had lower economic status
Selective reporting (reporting bias)	Unclear risk	Comment: no study protocol available
Other bias	Unclear risk	Comment: not reported in the publications why the duration of the intervention was prolonged. No data available after 6 years of intervention

Note: where the judgement is 'Unclear' and the description is blank, the study did not report that particular outcome.

- denotes not reported

ADA: American Diabetes Association; BMI: body mass index; CVD: cardiovascular disease; DBP: diastolic blood pressure; DM: diabetes mellitus; DPP: Diabetes Prevention Program; DPPA: diet plus physical activity; DPPOS: Diabetes Prevention Program Outcome Study; DPS: Diabetes Prevention Study; EDIPS: European Diabetes Prevention Study; FPG: fasting plasma glucose; HbA1c: glycosylated haemoglobin A1c; HELP PD: Healthy Living Partnerships to Prevent Diabetes; HRQoL: health-related quality of life; ICC: intra-cluster coefficient; IDPP: Indian Diabetes Prevention Programmes; IFG: impaired fasting glucose; IGT: impaired glucose tolerance; JDPP: Japan Diabetes Prevention Program; NYHA: New York Heart Association; OGTT: oral glucose tolerance test; PODOSA: Prevention of Diabetes and Obesity in South Asians; SBP: systolic blood pressure; SLIM: Study on Lifestyle-intervention and Impaired glucose tolerance Maastricht; T2DM: type 2 diabetes mellitus; WHO: World health Organization

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
APHRODITE	Included normoglycaemic people and people with intermediate hyperglycaemia. Participants have a high FIND-RISK score, but not necessarily intermediate hyperglycaemia
Bo 2007	The trial did not have intermediate hyperglycaemia as an inclusion criterion
D-CLIP	Duration of the intervention < 2 years
De la Rosa 2007	Not a randomised trial
DH!AAN	Outcomes only reported after 1 year of intervention Quote from publication: "At the time of registration of the trial, the intended primary outcome was the 3-year incidence of type 2 diabetes. However, as the initial response rate was lower than expected, the recruitment period had to be extended to 2 years. Due to a fixed end date of the study (grant restrictions), the follow-up time was reduced to 2 years. As this period was too short to properly investigate differences in incidence of type 2 diabetes between the control and intervention group, we changed the primary outcome to the more proximal outcomes, namely changes in weight and other weight-related measurements (body mass index, waist circumference, and fat mass) after 1 year. Secondary outcomes were changes in glucose metabolism, blood pressure, and lipid profile after 1 year."
E-LITE	Included participants with metabolic syndrome or intermediate hyperglycaemia
Eriksson 1991	Inadequate randomisation, the control group was not randomised
Eriksson 2006	Included participants with T2DM
Grey 2004	Both experimental and control groups received the same nutritional education and physical activity training
Hesselink 2013	Duration of the intervention < 2 years
Huang 2007	Duration of the intervention < 2 years
J-DOIT	Duration of the intervention < 2 years
Jarrett 1979	Not comparing intervention of interest (carbohydrate 120 g/day + placebo versus 'limit sucrose (i.e. table sugar) intake' + placebo)
Kawahara 2008	Duration of the intervention < 2 years
Kinmonth 2008	Included participants being overweight and having a parental history of diabetes - the number of participants with intermediate hyperglycaemia was not available. Duration of the intervention < 2 years

(Continued)

Let's Prevent	Same intensity of diet and physical activity was applied in the intervention and comparator group
Liao 2002	Not comparing intervention of interest (diet plus endurance physical activity versus diet plus stretching)
Lindahl 1999	Duration of the intervention < 2 years (intervention performed after 1 year was a telephone call at 24 months)
Marrero 2016	Duration of the intervention < 2 years
Nanditha 2014	Same intensity of diet and physical activity was applied in the intervention and comparator group
NCT02250066	Did not compare interventions of interest (mono-saturated fat versus high carbohydrate diet)
NCT02374788	Included participants with T2DM
Page 1992	Duration of the intervention < 2 years
PULSE	Same intensity of diet and physical activity in the intervention arms
Ramachandran 2013	Duration of the intervention < 2 years
Rosas 2016	Included participants with metabolic syndrome
Saito 2011	Same intensity of diet and physical activity was applied in the intervention and comparator group
Sartor 1980	No description of the diet-only group
Sathish 2017	Duration of the intervention < 2 years
Savoie 2007	Duration of the intervention < 2 years
Schmidt 2016	Included participants with gestational diabetes
SHINE	Included participants with metabolic syndrome
Tao 2004	Inadequate randomisation: quasi-randomised participants
The Fasting Hyperglycaemia Study 1997a	Not possible to get separate data on the participants with impaired glucose tolerance (Rury Holman was asked when request was made in another review (Hemmingen 2016)). This article describes 37% of participants with normal glucose tolerance, 26% with T2DM and 37% with impaired glucose tolerance

(Continued)

Thompson 2008	Duration of the intervention < 2 years
Villareal 2006	Duration of the intervention < 2 years
Wein 1999	Same intensity of diet and physical activity was applied in the intervention and comparator group
Wing 1998	Included participants being overweight and a parental history of diabetes - the number of participants with intermediate hyperglycaemia was not available
Wong 2013	Same intensity of diet and physical activity was applied in the intervention and comparator group
Yates 2011	Duration of the intervention < 2 years
Yates 2012	Intermediate hyperglycaemia was not an inclusion criterion

Characteristics of studies awaiting assessment [ordered by study ID]

130750-201504-HR-020

Methods	Parallel, randomised, controlled, clinical trial (RCT) Randomisation ratio: 1:1:1
Participants	Condition: IFG (5.6-6.9 mmol/L) or moderately elevated HbA1c (5.7%-6.4%) Enrollment: 1200 Inclusion criteria: IFG or moderately elevated HbA1c, 30-70 years
Interventions	Intervention 1: concealing of lifestyle modification aimed at reducing weight, total intake of carbohydrate, fat and saturated fat, increasing intake of fibre and physical activity level Intervention 2: periodic health examination during a 3-month period for monitoring fasting blood glucose and HbA1c Comparator: periodic health examination during a 1-year period for checking health status about T2DM Duration of the intervention: not clearly described
Outcomes	Primary outcome(s): HbA1c Secondary outcome(s): fasting blood glucose Other outcome(s): -
Notes	Study protocol for an ongoing trial. Not possible to estimate the duration of the intervention from the study protocol. Investigators were asked, but no reply

ChiCTR-PRC-13003267

Methods	Parallel, randomised, controlled, clinical trial (RCT) Randomisation ratio: 1:1
Participants	Condition: IGT and/or IFG Enrollment: not reported Inclusion criteria: Chinese, 40-69 years, IGT and/or IFG and < 150 min/week of moderate/vigorous physical activity
Interventions	Intervention: individualised physical activity plan Comparator: not specified Duration of the intervention: not clearly described
Outcomes	Primary outcome(s): - Secondary outcome(s): - Other outcome(s): physical activity level and blood glucose level
Notes	Study protocol for an ongoing trial. Not possible to estimate the duration of the intervention from the study protocol. Priority of outcomes not described in protocol. Investigators were asked, but no reply

iHealth-T2D

Methods	Parallel, randomised, controlled, clinical trial (RCT) Randomisation ratio: 1:1
Participants	Condition: waist circumference \geq 100 cm or HbA1c \geq 6.0% Enrollment: 3600 Inclusion criteria: waist circumference \geq 100 cm or HbA1c \geq 6.0%; South Asian, 40-70 years
Interventions	Intervention: intensive lifestyle modification Comparator: usual care Duration of the intervention: assume 1 year
Outcomes	Primary outcome(s): incidence of T2DM and > 7% reduction in weight Secondary outcome(s): reduction of \geq 5 cm waist circumference and health gains in family members Other outcome(s): identifying social, demographic and environmental factors influencing primary and secondary outcomes
Notes	Protocol for an ongoing trial. Unknown if data would be presented for the participants included based on moderately elevated HbA1c. Duration of the intervention might be too short for inclusion in this review

NDPS

Methods	Parallel, randomised, controlled, clinical trial (RCT) Randomisation ratio: 1:1
Participants	Condition: HbA1c \geq 6.0 to < 6.5% and a normal fasting plasma glucose (< 5.6 mmol/L) Enrollment: - Inclusion criteria: HbA1c \geq 6.0 to < 6.5%

NDPS (Continued)

Interventions	Intervention: intensive diet plus physical activity advice Comparator: standard control Duration of the intervention: 40 months
Outcomes	Primary outcome(s): HbA1c Secondary outcome(s): homeostasis model assessment, physical activity levels, dietary intake, weight, body fat mass, visceral fat, BMI and waist circumference and health status Other outcome(s): -
Notes	A fraction of participants in an ongoing randomised clinical trial

Zong 2015

Methods	Parallel, randomised, controlled, clinical trial (RCT) Randomisation ratio: 1:1
Participants	Condition: IFG (6.1-6.9 mmol/L) and/or IGT (2-h OGTT 7.8-11.0 mmol/L) Enrollment: 214 Inclusion criteria: IFG and/or IGT
Interventions	Intervention: not described Comparator: not described Duration of the intervention: 2 years
Outcomes	Primary outcome(s): HbA1c Secondary outcome(s): homeostasis model assessment, physical activity levels, dietary intake, weight, body fat mass, visceral fat, BMI and waist circumference and health status Other outcome(s): -
Notes	We are currently searching for Chinese authors to help clarify the intervention

HbA1c: glycosylated haemoglobin A1c; IFG: impaired fasting glucose; IGT: impaired glucose tolerance; OGTT: oral glucose tolerance test; PDPP: Pakistan Diabetes Prevention Program; T2DM: type 2 diabetes mellitus

Characteristics of ongoing studies [ordered by study ID]

NCT01530165

Trial name or title	Acronym: PDPP
Methods	Type of study: efficacy study Allocation: randomised Intervention model: parallel assignment Masking: open-label Primary purpose: prevention

NCT01530165 (Continued)

Participants	<p>Condition: impaired glucose tolerance (WHO) Enrollment: 20,000 Inclusion criteria: IGT; 30-64 yrs Exclusion criteria: T1DM; T2DM; pregnancy; presence of chronic disease rendering survival for 3 years unlikely; any psychological or physical disability to interfere with participation in the trial; ischaemic heart disease</p>
Interventions	<p>Intervention(s): aggressive lifestyle intervention consisting of nutritional and physical activity advice Comparator(s): standard advice Duration of the intervention: 2 years</p>
Outcomes	<p>Primary outcome(s): incidence of T2DM Secondary outcome(s): cost effectiveness; components of the metabolic syndrome; the impact of city planning on prevalence of obesity and T2DM Other outcome(s): -</p>
Starting date	<p>Study start date: 2011 Study completion date: June 2017</p>
Contact information	<p>Responsible party/principal investigator: Asma Ahmed, Aga Khan University</p>
Study identifier	<p>NCT number: NCT01530165</p>
Official title	<p>Pakistan Diabetes Prevention Program</p>
Stated purpose of study	<p>Quote from publication: "The Karachi-based Pakistan Diabetes Prevention Study aims to address key issues in the prevention of type 2 diabetes "</p>
Notes	<p>The study completion date is provided by the principal investigator. Conducted in Pakistan</p>

PREVIEW

Trial name or title	<p>Acronym: PREVIEW</p>
Methods	<p>Type of study: efficacy study Allocation: randomised Intervention model: parallel assignment Masking: open-label Primary purpose: prevention</p>
Participants	<p>Condition: IFG or IGT (IFG: fasting venous plasma glucose concentration 5.6-6.9 mmol/L or IGT: venous plasma glucose concentration of 7.8-11.0 mmol/L at 2-h after oral administration of 75 g glucose with fasting plasma glucose less than 7.0 mmol/L) Enrollment: 2500 Inclusion criteria: age 25-70 years; overweight or obesity (BMI > 25 kg/m²); IFG or IGT; informed consent required; provided participants have not recently (within 1 month) changed habits; motivation and willingness to be randomised to any of the groups and to do his/her best to follow the given protocol Exclusion criteria: diabetes mellitus (other than gestational diabetes mellitus); significant cardiovascular</p>

	<p>disease including current angina; myocardial infarction or stroke within the past 6 months; heart failure; symptomatic peripheral vascular disease; systolic blood pressure above 160 mmHg and/or diastolic blood pressure above 100 mmHg whether on or off treatment for hypertension. If being treated, no change in drug treatment within last 3 months; advanced chronic renal impairment; significant liver disease e.g. cirrhosis (fatty liver disease allowed); malignancy which is currently active or in remission for < 5 years after last treatment (local basal and squamous cell skin cancer allowed); active inflammatory bowel disease, celiac disease, chronic pancreatitis or other disorder potentially causing malabsorption; previous bariatric surgery; chronic respiratory, neurological, musculoskeletal or other disorders where, in the judgement of the investigator, participants would have unacceptable risk or difficulty in complying with the protocol (e.g. physical activity programme); a recent surgical procedure until after full convalescence (investigator judgement); transmissible blood-borne diseases; psychiatric illness (e.g. major depression, bipolar disorder); use currently or within the previous 3 months of prescription medication that has the potential of affecting body weight or glucose metabolism such as glucocorticoids (but excluding inhaled and topical steroids; bronchodilators are allowed); psychoactive medication, epileptic medication, or weight loss medications (either prescription, over the counter or herbal). Low-dose antidepressants are allowed if they, in the judgement of the investigator, do not affect weight or participation to the study protocol. Levothyroxine for treatment of hypothyroidism is allowed if the participant has been on a stable dose for at least 3 months; engagement in competitive sports; self-reported weight change of > 5% (increase or decrease) within 2 months prior to screening; special diets within 2 months prior to study start; severe food intolerance expected to interfere with the study; regularly drinking > 21 alcoholic units/week (men), or > 14 alcoholic units/week (women); use of drugs of abuse within the previous 12 months; blood donation or transfusion within the past 1 month before baseline; self-reported eating disorders; pregnancy or lactation, including plans to become pregnant within the next 36 months; no access to either phone or Internet (this is necessary when being contacted by the instructors during the maintenance phase); adequate understanding of national language; psychological or behavioural problems which, in the judgement of the investigator, would lead to difficulty in complying with the protocol; haemoglobin concentration below local laboratory reference values (i.e. anaemia); creatinine > 1.5 times Upper Limit of Normal (local laboratory reference values); alanine transaminase and/or aspartate transaminase > 3 times the Upper Limit of Normal (local laboratory reference values) or any other significant abnormality on these tests which in the investigators opinion may be clinically significant and require further assessment; electrocardiography. Any abnormality which in the opinion of the investigator might indicate undiagnosed cardiac disease requiring further assessment (e.g. significant conduction disorder, arrhythmia, pathological Q waves). This is done in adults 55-70 years of age</p>
Interventions	<p>Intervention(1): high protein/high-intensity physical activity Intervention(2): high protein/moderate-intensity physical activity Intervention(3): moderate protein/high-intensity physical activity Intervention(4): moderate protein/moderate-intensity physical activity Comparator(s): participants follow a moderate protein diet and moderate-intensity physical activity intervention Duration of the intervention: 3 years</p>
Outcomes	<p>Primary outcome(s): incidence of T2DM Secondary outcome(s): HbA1c; change in body weight and waist, hip and thigh circumference; change in body fat mass (kg, proportion of body weight); proportion of participants maintaining at least 0%, 5% or 10% weight loss (relative to initial body weight); insulin sensitivity; risk factors for cardiovascular disease, with at least the following measures: blood pressure, lipids (triglycerides, total, low-density lipoprotein and high-density lipoprotein cholesterol), C-reactive protein, and liver enzymes; changes in perceived quality of life and work ability, habitual well-being, sleep and chronic stress, subjective appetite sensations, and</p>

PREVIEW (Continued)

	habitual physical activity; the effects of stature (height; proportion leg-length/height) in adults and changes in stature in children and adolescents, on the changes in relationship between reduction in body weight, body fat and insulin sensitivity Other outcome(s): -
Starting date	Study start date: June 2013 Study completion date: December 2018
Contact information	Responsible party/principal investigator: Anne Birgitte Raben, Professor, University of Copenhagen
Study identifier	NCT number: NCT01777893
Official title	PREvention of Diabetes Through Lifestyle Intervention and Population Studies in Europe and Around the World
Stated purpose of study	Quote: “Our hypothesis is that a high-protein, low-GI diet will be superior in preventing type-2 diabetes, compared with a moderate protein, moderate GI diet, and that high-intensity physical activity will be superior compared to moderate-intensity physical activity”
Notes	-

PROPELS

Trial name or title	Acronym: PROPELS
Methods	Type of study: efficacy study Allocation: randomised Intervention model: parallel assignment Masking: open-label Primary purpose: prevention
Participants	Condition: intermediate hyperglycaemia Enrollment: 1308 Inclusion criteria: 40-74 years old for white European, or aged 25-74 years old for South Asian; previously recorded plasma glucose or HbA1c value in the prediabetes range within the last 5 years; have access to a mobile phone, and willing to use it as part of the study Exclusion criteria: due to the nature of the intervention those unable to undertake ambulatory-based activity will be excluded; T2DM; screen-detected diabetes at baseline; pregnancy; normoglycaemia with no previous record of intermediate hyperglycaemia in the previous 5 years
Interventions	Intervention(s): diet as the comparator group, but additional physical activity provided Comparator(s): receive a booklet detailing information on risk factors for T2DM and cardiovascular disease and how physical activity can be used to prevent T2DM and cardiovascular disease Duration of the intervention: 48 months
Outcomes	Primary outcome(s): change in ambulatory activity Secondary outcome(s): time spent in sedentary, light, moderate and vigorous intensity physical activity assessed by accelerometer and self report; website use and text messages sent/received (intervention group)

PROPELS (Continued)

	3 only); fasting and 2-h post-challenge glucose and HbA1c; fasting lipid profile, fasting insulin, highly sensitive C-reactive protein, key adipokines (interleukin 6 and tumour necrosis factor alpha), urea and electrolytes (sodium, potassium, urea, creatinine) and liver function tests; markers of chronic inflammation and adipokines; vitamin C and D; genetic analysis; urine sample; height; body weight; BMI; body fat percentage; waist circumference; arm and leg length; blood pressure; medication status; smoking status; family history of disease; muscular/skeletal injury; illness perceptions; self efficacy; self regulation; quality of life; depression and anxiety; diet; sleep; body composition Other outcome(s):-
Starting date	Study start date: August 2013 Study completion date: August 2018
Contact information	Responsible party/principal investigator: University of Leicester, UK
Study identifier	ISRCTN: 83465245
Official title	The PRomotion Of Physical activity through structured Education with differing Levels of ongoing Support for those with pre-diabetes
Stated purpose of study	Quote: “Can an intervention to support physical activity behaviour change lead to sustained increases in physical activity over four years in those with a high risk of type 2 diabetes.”
Notes	-

BMI: body mass index; HbA1c: glycosylated haemoglobin A1c; IFG: impaired fasting glucose; IGT: impaired glucose tolerance; T1DM: type 1 diabetes mellitus; T2DM: type 2 diabetes mellitus

DATA AND ANALYSES

Comparison 1. Physical activity versus comparator

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 All-cause mortality	2		Risk Ratio (M-H, Random, 95% CI)	Subtotals only
2 Incidence of type 2 diabetes	2		Risk Ratio (M-H, Random, 95% CI)	Subtotals only
3 Serious adverse events	2		Risk Ratio (M-H, Random, 95% CI)	Subtotals only
4 Fasting plasma glucose	2		Mean Difference (IV, Random, 95% CI)	Subtotals only
5 2 hour glucose values	2		Mean Difference (IV, Random, 95% CI)	Subtotals only

Comparison 2. Diet plus physical activity versus comparator

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 All-cause mortality	10	4099	Risk Ratio (M-H, Random, 95% CI)	1.12 [0.50, 2.50]
2 All-cause mortality: duration of intervention	10	4099	Risk Ratio (M-H, Random, 95% CI)	1.12 [0.50, 2.50]
2.1 ≥ 4 years	3	817	Risk Ratio (M-H, Random, 95% CI)	1.32 [0.33, 5.28]
2.2 < 4 years	7	3282	Risk Ratio (M-H, Random, 95% CI)	1.03 [0.38, 2.77]
3 All-cause mortality: diagnostic criteria	10	4099	Risk Ratio (M-H, Random, 95% CI)	1.12 [0.50, 2.50]
3.1 IGT	9	3798	Risk Ratio (M-H, Random, 95% CI)	1.12 [0.50, 2.50]
3.2 Other criteria	1	301	Risk Ratio (M-H, Random, 95% CI)	0.0 [0.0, 0.0]
4 All-cause mortality: age	10	4099	Risk Ratio (M-H, Random, 95% CI)	1.12 [0.50, 2.50]
4.1 Age ≥ 50 years	8	3682	Risk Ratio (M-H, Random, 95% CI)	1.02 [0.39, 2.66]
4.2 Age < 50 years	2	417	Risk Ratio (M-H, Random, 95% CI)	1.40 [0.32, 6.16]
5 All-cause mortality: sex	10	4099	Risk Ratio (M-H, Random, 95% CI)	1.12 [0.50, 2.50]
6 All-cause mortality: ethnicity	10	4099	Risk Ratio (M-H, Random, 95% CI)	1.12 [0.50, 2.50]
6.1 Asian	4	797	Risk Ratio (M-H, Random, 95% CI)	1.27 [0.37, 4.39]
6.2 (Predominantly)White	6	3302	Risk Ratio (M-H, Random, 95% CI)	1.02 [0.36, 2.94]
7 All-cause mortality: obesity	10	4099	Risk Ratio (M-H, Random, 95% CI)	1.12 [0.50, 2.50]
7.1 BMI ≥ 30	6	3322	Risk Ratio (M-H, Random, 95% CI)	1.02 [0.36, 2.94]
7.2 BMI < 30	4	777	Risk Ratio (M-H, Random, 95% CI)	1.27 [0.37, 4.39]
8 Incidence of type 2 diabetes	11	4511	Risk Ratio (M-H, Random, 95% CI)	0.57 [0.50, 0.64]
9 Incidence of type 2 diabetes: duration of the intervention	11	4511	Risk Ratio (M-H, Random, 95% CI)	0.57 [0.50, 0.64]
9.1 Long duration (≥ 4 years)	4	1249	Risk Ratio (M-H, Random, 95% CI)	0.55 [0.41, 0.74]
9.2 Short duration (< 4 years)	7	3262	Risk Ratio (M-H, Random, 95% CI)	0.57 [0.48, 0.67]
10 Incidence of type 2 diabetes: diagnostic criteria	11	4511	Risk Ratio (M-H, Random, 95% CI)	0.57 [0.50, 0.64]
10.1 IGT	10	4210	Risk Ratio (M-H, Random, 95% CI)	0.57 [0.50, 0.66]
10.2 Other criteria	1	301	Risk Ratio (M-H, Random, 95% CI)	0.36 [0.12, 1.11]

Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus (Review) 120

Analysis 1.1. Comparison 1 Physical activity versus comparator, Outcome 1 All-cause mortality.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 1 Physical activity versus comparator

Outcome: 1 All-cause mortality

(1) After 6 yrs of intervention; corrected with design effect of 1.75

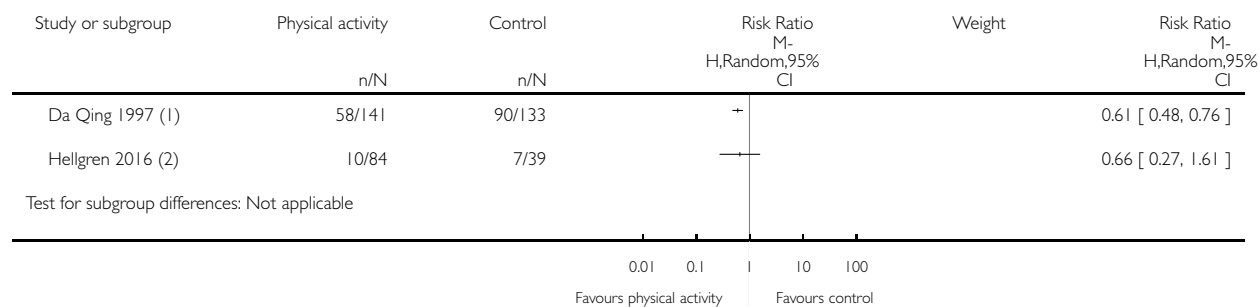

(2) Data provided by the investigators

Analysis 1.2. Comparison 1 Physical activity versus comparator, Outcome 2 Incidence of type 2 diabetes.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 1 Physical activity versus comparator

Outcome: 2 Incidence of type 2 diabetes

(1) After 6 yrs of intervention; corrected with design effect of 1.75

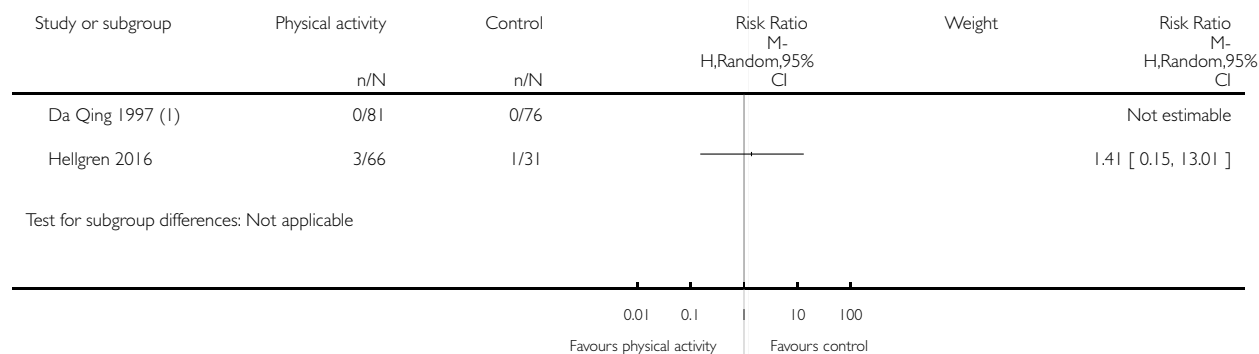

(2) After 3 years of intervention

Analysis 1.3. Comparison 1 Physical activity versus comparator, Outcome 3 Serious adverse events.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 1 Physical activity versus comparator

Outcome: 3 Serious adverse events

(1) After 6 yrs of intervention

Analysis 1.4. Comparison 1 Physical activity versus comparator, Outcome 4 Fasting plasma glucose.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 1 Physical activity versus comparator

Outcome: 4 Fasting plasma glucose

(1) End of FU values after 6 yrs of intervention; adjusted for clustering

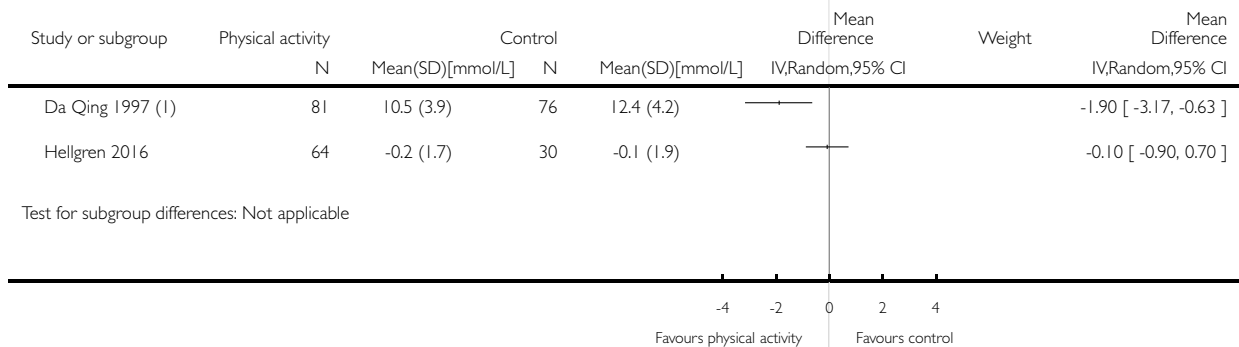

(2) Data provided by investigators

Analysis 1.5. Comparison 1 Physical activity versus comparator, Outcome 5 2 hour glucose values.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 1 Physical activity versus comparator

Outcome: 5 2 hour glucose values

(1) End of FU values after 6 yrs of intervention; adjusted for clustering

Analysis 2.1. Comparison 2 Diet plus physical activity versus comparator, Outcome 1 All-cause mortality.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 2 Diet plus physical activity versus comparator

Outcome: 1 All-cause mortality

(1) Adjusted for clustering

(2) Estimated cumulative mortality at three years

(3) Data provided by authors

Analysis 2.2. Comparison 2 Diet plus physical activity versus comparator, Outcome 2 All-cause mortality: duration of intervention.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 2 Diet plus physical activity versus comparator

Outcome: 2 All-cause mortality: duration of intervention

(1) adjusted for clustering

(2) Estimated cumulative mortality at three years

(3) Data provided by authors

Analysis 2.3. Comparison 2 Diet plus physical activity versus comparator, Outcome 3 All-cause mortality: diagnostic criteria.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 2 Diet plus physical activity versus comparator

Outcome: 3 All-cause mortality: diagnostic criteria

Analysis 2.4. Comparison 2 Diet plus physical activity versus comparator, Outcome 4 All-cause mortality: age.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 2 Diet plus physical activity versus comparator

Outcome: 4 All-cause mortality: age

(1) Estimated cumulative mortality at three years

(2) Data provided by authors

(3) adjusted for clustering

Analysis 2.5. Comparison 2 Diet plus physical activity versus comparator, Outcome 5 All-cause mortality: sex.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 2 Diet plus physical activity versus comparator

Outcome: 5 All-cause mortality: sex

(1) adjusted for clustering

(2) Estimated cumulative mortality at three years

(3) Data provided by authors

Analysis 2.6. Comparison 2 Diet plus physical activity versus comparator, Outcome 6 All-cause mortality: ethnicity.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 2 Diet plus physical activity versus comparator

Outcome: 6 All-cause mortality: ethnicity

(1) adjusted for clustering

(2) Estimated cumulative mortality at three years

(3) Data provided by authors

Analysis 2.7. Comparison 2 Diet plus physical activity versus comparator, Outcome 7 All-cause mortality: obesity.

Review: Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus

Comparison: 2 Diet plus physical activity versus comparator

Outcome: 7 All-cause mortality: obesity

Table 1. Overview of trial populations (Continued)

<i>All comparators</i>	3091
<i>All interventions and comparators</i>	5238 ^d

“-” denotes not reported

^aRandomised numbers in each group not specified.

^bAfter 6 years of intervention, during the subsequent 17-year follow-up period after the intervention had stopped 6 participants were lost to follow-up.

^cOf the 1082 participants assigned to placebo, 1052 were available for the DPPOS (see DPP 2002); of these 935 were enrolled in the DPPOS. Of the 1079 assigned to the behaviour changing intervention 1042 were available for the DPPOS; of these 915 were enrolled in the DPPOS.

^dTrial authors state that ITT analysis was performed but data are presented as a per-protocol analysis.

^eData for the end of intervention. Participants included in the extension period were 200 in the intervention group and 166 in the control group.

^fNumber of analysed participants varied during the trial (intervention group: 39 at 1 year; 35 at 2 years; 27 at 3 years; 28 at 4 years; 21 at 5 years; control group: 43 at 1 year; 37 at 2 years; 33 at 3 years; 28 at 4 years; 21 at 5 years).

^g123 participants were eligible for the trial, 4 died and 10 developed T2DM and did not complete the final examination. One received a gastric bypass; 17 refused follow-up. Not specified to which intervention groups these people were randomised.

^hNumber of analysed participants varied during the trial (intervention group: 139 at 6 months, 135 at 12 months, 125 at 18 months and 127 at 24 months; control group: 141 at 6 months, 138 at 12 months, 132 at 18 months and 134 at 24 months).

ⁱNumber of analysed participants varied during the trial (intervention group: 37 at 6 months, 32 at 12 months and 30 at 24 months; control group: 32 at 6 months, 30 at 12 months and 24 at 24 months).

^j78 families with 85 participants and 55 family volunteers were allocated to the intervention, 78 families with 86 participants and 69 family volunteers were allocated to the control.

^kNumber of analysed participants varied during the trial (intervention group: 52 at 3 years, 51 at 4 years, 34 at 5 years and 35 (one that was missing at 6 years attended 6-year follow-up) at 6 years; control group: 54 at 3 years, 43 at 4 years, 29 at 5 years and 35 (6 that were missing at five years attended 6-year follow-up) at 6 years).

^l2 trials did not report the number of randomised participants per intervention group. Therefore, numbers do not add up accurately. DPP: Diabetes Prevention Program; DPPOS: Diabetes Prevention Program Outcome Study; EDIPS: European Diabetes Prevention Study; HELP PD: Healthy Living Partnerships to Prevent Diabetes; IDPP: Indian Diabetes Prevention Programmes; ITT: intention-to-treat; JDPP: Japan Diabetes Prevention Program; PODOSA: Prevention of Diabetes and Obesity in South Asians; RCT: randomised controlled trial; SLIM: Study on Lifestyle-intervention and Impaired glucose tolerance Maastricht

Appendix 2. Description of interventions

Trial ID	Intervention(s)	Intervention(s) appropriate as applied in a clinical practice setting ^a (description)	Comparator(s)	Comparator(s) appropriate as applied in a clinical practice setting ^a (description)
Da Qing 1997	<p>I1: diet: participants with BMI < 25 kg/m² were prescribed a diet containing 25-30 kcal/kg body wt (105-126 kj/kg), 55%-65% carbohydrate, 10%-15% protein, and 25%-30% fat. These participants were encouraged to consume more vegetables, control their intake of alcohol, and reduce their intake of simple sugars.</p> <p>Participants with BMI > 25 kg/m² were encouraged to reduce their calorie intake so as to gradually lose weight at a rate of 0.5-1.0 kg per month until they achieved a BMI of 23 kg/m²</p> <p>Group/individual: both Medium: group Facilitator: physician Frequency: weekly for one month, monthly for three months, and then once ev-</p>	Intensified diet and/or physical activity is an appropriate comparator	<p>Standard recommendation: received general information about diabetes and impaired glucose tolerance. Were provided brochures with general instructions for diet and physical activities</p> <p>Group/individual: no formal group or individual counselling were performed</p> <p>Medium: group Facilitator: not specified Frequency: no formal sessions arranged</p> <p>Extended FU period: no intervention provided. Examination after 20 years and 23 years of follow-up</p>	Standard diet and physical activity recommendation is an appropriate comparator

(Continued)

<p>ery third month for the remainder of the six years' intervention period (30 visits)</p> <p>Extended FU period: no intervention provided. Examination after 20 years and 23 years of follow-up</p> <hr/>			
<p>I2: physical activity: participants in clinics assigned to the physical activity group were taught and encouraged to increase the amount of their leisure physical activity by at least 1 unit/day (mild-moderate-strenuous and very strenuous) and by 2 units/day if possible for those < 50 years of age with no evidence of cardiovascular disease or arthritis</p> <p>Group/individual: both Medium: group Facilitator: not specified Frequency: weekly for one month, monthly for three months, and then once every third month for the remainder of the six years' intervention period (30 visits)</p> <p>Extended FU period: no intervention provided. Examination after 20 years and 23 years of follow-up</p> <hr/>			
<p>I3: diet plus physical activity: diet as described for the diet group (I1) combined with physical activity (I2)</p> <p>Group/individual: both Medium: group Facilitator: physician Frequency: weekly for one</p>			

(Continued)

	<p>month, monthly for three months, and then once every third month for the remainder of the six years' intervention period (30 visits)</p> <p>Extended FU period: no intervention provided. Examination after 20 years and 23 years of follow-up</p>			
DPP 2002	<p>Diet plus physical activity intervention: healthy, low-calorie, low-fat diet</p> <p>Physical activity intervention: moderate intensity for at least 150 minutes per week</p> <p>The aim was to achieve and maintain a weight reduction of at least 7% of initial body weight through physical activity and diet. A 16-lesson programme covering diet, physical activity, and behaviour modification was applied during the first 24 weeks after enrolment was flexible and individualised. Subsequent individual sessions (usually monthly) were designed to reinforce the behavioural changes</p> <p>Group/individual: both</p> <p>Medium: in person</p> <p>Facilitator: case manager ("lifestyle coach"), usually a dietitian</p> <p>Frequency: 40 (16 lessons in first 24 weeks, then monthly)</p> <p>Extended FU period: lifestyle sessions were offered to all participants every 3rd month</p>	<p>Intensified diet and physical activity is an appropriate comparator</p>	<p>Placebo + standard recommendation</p> <p>Standard diet intervention: culturally sensitive materials and motivational strategies</p> <p>Standard physical activity intervention: participants were encouraged to increase their activity gradually and to try to reach the goal of at least 30 minutes of physical activity (such as walking or biking) on 5 days each week</p> <p>Written information and annual 30 min individual session on healthy lifestyles. Changes in dietary and physical activity recommended for weight loss for overweight and obese participants</p> <p>Group/individual: both (At the first visit, the staff will spend approximately 20 - 30 minutes with each participant individually)</p> <p>Medium: in person</p> <p>Facilitator: staff (not described further)</p> <p>Frequency: annually (three times)</p> <p>Extended FU period: lifestyle sessions were offered to all participants every 3rd month</p>	<p>Standard diet and physical activity recommendation is an appropriate comparator</p>

(Continued)

	with educational material and reinforcement of original weight loss and physical activity goals. DPP lifestyle participants were also offered two group classes comprising four sessions every year in order to reinvigorate their self-management behaviours for weight loss. Yearly visits		with educational material and reinforcement of original weight loss and physical activity goals. Yearly visits	
DPS 2001	<p>Diet plus physical activity Dietary intervention: baseline three-day food record was completed before first appointment. The participants were advised to consume a diet with more than 50% of daily calories from carbohydrates; less than 10% from saturated fat and 20% from mono- and polyunsaturated fat, or up to 25% if the surplus is from monounsaturated fat; cholesterol less than 300 mg/day; and approximately 1.0 g protein per kg ideal body weight per day. The increase in the intake of dietary fibre to 15 g per 1000 kcal or more was encouraged</p> <p>It was aimed to reduce the intake of saturated fat and participants are encouraged to use low-fat milk and milk products, low-fat meat and meat products, soft margarines and vegetable oil rich in monounsaturated fatty acids (primarily rapeseed oil)</p> <p>If weight loss was not</p>	Intensified diet and physical activity is an appropriate comparator	<p>Standard recommendation Standard diet intervention: adjust total energy intake in order to reduce BMI below 25 kg/m² and to keep to a diet with less than 30% of daily energy from fat. Advised to reduce alcohol intake and to stop smoking as appropriate. The dietary advice is provided by verbal and written information</p> <p>Standard physical activity intervention: verbal general information about the health effects of recreational physical activity was provided but no specific individual propositions and programmes were given</p> <p>Group/individual: both Medium: in person Facilitator: nutritionist Frequency: advice given initially and in annual follow-up visits No of contacts: four</p> <p>Extended FU period: yearly visit by a nurse, no specific diet or physical activity counselling was provided</p>	Standard diet and physical activity recommendation is an appropriate comparator

(Continued)

	<p>achieved during the first 6-12 months and the BMI was over 30 kg/m², a very low-calorie diet was considered.</p> <p>Physical activity intervention: guided to increase their physical activity. Exercise programmes differed among study centres according to local situation and facilities. Endurance exercise (walking, jogging, swimming, aerobic ball games, skiing) was recommended to increase aerobic capacity and cardiorespiratory fitness. Supervised, progressive, individually tailored circuit-type resistance training sessions were organised, if possible, twice a week. The moderate intensity and medium- to high-volume programmes were designed to improve the functional capacity and strength of the large muscle groups of the upper and lower body</p> <p>The aim was a BMI of less than 25 kg/m² but, in practice, a weight loss of 5 to 10 kg depending on degree of obesity was the target for many study participants</p> <p>Group/individual: both (the person primarily in charge of preparing meals in the family, if different from the study participant, was also informed about the study aims and invited to join in the sessions with the nutritionist or the group meetings)</p>

(Continued)

<p>HELP PD 2011</p>	<p>Diet plus physical activity The goal was weight loss 5% to 7% The intervention was divided into two phases First phase dietary intervention (month 1-6): reduction of intake by 500-1000 kcal per day; reduction in total fats to 25%-30%, saturated fats to 7%, and protein to 15% of intake; increase in fruit and vegetable consumption to 5 servings per day; intake of ≥ 3 whole grain servings per day The first phase physical activity intervention (month 1-6): gradual progression to 180 minutes of moderate intensity physical activity per week (e.g. 30 min/day of walking, 6 days/week) Second phase dietary intervention (month 7-24) : isocaloric intake tailored to maintenance of lost weight; maintenance of 25%-30% energy intake from total fats, 7% from saturated fat, and 15% from protein; continued daily intake of 5 fruits and vegetables and ≥ 3 whole grain servings The second phase physical activity intervention (month 7-24): maintenance of 180 min of moderate intensity physical activity per week; coping with injuries and other barriers to the maintenance</p>	<p>Intensified diet and physical activity is an appropriate comparator</p>	<p>Standard recommendation Information about healthy eating and activity to support weight loss, and discuss existing community resources that may fit the individual needs of comparison participants as they pursue dietary change, increased physical activity and weight loss Group/individual: individual Medium: in person Facilitator: dietician Frequency: two individual sessions with a nutritionist during the first 3 months, In addition, comparison participants receive a quarterly newsletter with topics related to healthy lifestyle No. of contacts: 6</p>	<p>Standard diet and physical activity recommendation is an appropriate comparator</p>
----------------------------	---	--	--	--

(Continued)

	<p>nance of physical activity Group/individual: both Medium: in person Facilitator: community health workers, dietician Frequency: in the first intervention phase then 1 group session per week (for 6 months). In addition, all participants receive three personalised consultations with a dietician. During phase 2 (months 7-24), participants had 2 scheduled contacts with the community health worker each month, one group session and one phone contact No. of contacts: 46</p>			
IDPP 2006	<p>Diet plus physical activity Dietary intervention: diet modification with reduction in total calories, refined carbohydrates and fats, avoidance of sugar and inclusion of fibre-rich food Physical activity intervention: participants who were involved in physical labour or who had to walk or cycle for > 30 min/day or were performing physical activities regularly were asked to continue their routine activities. Participants engaged in sedentary or light physical activity were advised and regularly motivated to walk briskly for at least 30 min each day The intervention was explained individually at the time of randomisation, then again by phone or letter after 2</p>	Intensified diet and physical activity is an appropriate comparator	Standard recommendation standard health care advice Group/individual: both Medium: in person Facilitator: physician dietician and social worker Frequency: once a year No. of contacts: 3	Standard diet and physical activity recommendation is an appropriate comparator

(Continued)

	<p>weeks; thereafter monthly telephonic contacts were maintained for continued motivation. Personal sessions were conducted at 6-monthly intervals</p> <p>Group/individual: both</p> <p>Medium: in person</p> <p>Facilitator: physician dietician and social worker</p> <p>Frequency: every 6 months</p> <p>No. of contacts: 6</p>			
JDPP 2013	<p>Diet plus physical activity</p> <p>The goals of intervention were: 1) to reduce initial body weight by 5% in overweight and obese participants, and 2) to increase energy expenditure due to leisure time physical activity by 700 kcal per week</p> <p>The interventions were carried out by the study nurse in each collaborative centre in the form of both group and individual sessions, using the guideline, curriculum, and educational materials provided by the committee of the study group. When needed, the study nurse could ask a part-time dietician for diet counselling. A 27-page booklet titled "Change Your Lifestyle to Prevent Diabetes" was given to each participant as a guide</p> <p>Data on dietary intake and physical activities were assessed by the study group and the results were sent back to study nurses at each collaborative center</p>	<p>Intensified diet and physical activity is an appropriate comparator</p>	<p>Standard recommendation</p> <p>general verbal and written information on a healthy lifestyle and diabetes in one group session</p> <p>Group/individual: group</p> <p>Medium: in person</p> <p>Facilitator: public health nurses or dietician</p> <p>Frequency: one time</p> <p>No. of contacts: 1</p>	<p>Standard diet and physical activity recommendation is an appropriate comparator</p>

(Continued)

	<p>Dietary intervention: participants were advised to take the proper amount of calories, decrease the mean percent of energy derived from dietary fat to less than 25%, and restrict daily alcohol consumption to less than 160 kcal. They were also advised to eat three meals a day and avoid eating late at night</p> <p>Physical activity intervention: personalised goals, such as a minimum of 20 minutes' moderate walking each day, were set</p> <p>Group/individual: both Medium: in person Facilitator: public health nurses or dietician Frequency: during the initial six months, four group sessions were conducted. The individual sessions were conducted biannually during the three years with each session lasting 20-40 minutes. To reinforce the intervention, between-visit contact by fax was also made monthly during the initial twelve months. No. of contacts: 10 (excluding fax contact)</p>			
<p>Kosaka 2005</p>	<p>Diet plus physical activity Participants with a BMI ≥ 22 kg/m² were advised to lose weight, participants with BMI less than 22 kg/m² were advised to maintain their present weight. Family members were participating in the education</p>	<p>Intensified diet and physical activity is an appropriate comparator</p>	<p>Standard recommendation Standard diet intervention: participants with a BMI ≥ 24 kg/m² were advised to take 5%-10% smaller meals than they had been taking, and to increase their physical activity. They were encouraged</p>	<p>Standard diet and physical activity recommendation is an appropriate comparator</p>

(Continued)

	<p>of the participants</p> <p>Dietary intervention: eating smaller meals (reduce amount about 10%) , consume large amount of vegetables, reduce consumption of fat-rich foods</p> <p>Physical activity intervention: physical activity: walking 30-40 min/day; besides advice on how to increase physical activity during the day (e.g. taking staircase instead of an escalator etc.)</p> <p>Frequency: every 3-4 months</p> <p>No. of contacts: 16</p> <p>Group/individual: individual</p> <p>Medium: in person</p> <p>Facilitator: -</p>		<p>to lose weight</p> <p>Participants with a BMI < 24 kg/m² were told to avoid gaining weight by dieting and physical activity</p> <p>Standard physical activity intervention: participants with a BMI ≥ 24 kg/m² were advised to increase physical activity. They were encouraged to lose weight</p> <p>Participants with a BMI < 24 kg/m² were told to avoid gaining weight by dieting and physical activity</p> <p>Frequency: every 6 months</p> <p>No. of contacts: 8</p> <p>Group/individual: individual</p> <p>Medium: in person</p> <p>Facilitator: -</p>	
Oldroyd 2005	<p>Diet plus physical activity</p> <p>Dietary intervention: participants were encouraged to eat regular meals, eat more fruit and vegetables, reduce the fat content of foods, reduce sugar intake and eat adequate dietary fibre. The goal was to reduce BMI to < 25 kg/m² in those who were overweight or obese, to achieve a dietary fat intake of 30% of total energy intake, a polyunsaturated to saturated fat ratio of 1.0, 50% of energy from carbohydrate and a dietary fibre intake of 20 g per 4.2 MJ. All participants in the intervention group were given written</p>	<p>Intensified diet and physical activity is an appropriate comparator</p>	<p>No intervention</p> <p>Participants in the control group were offered no dietary or physical activity advice for the duration of the study</p> <p>Frequency: none</p> <p>No. of contacts: none</p> <p>Group/Individual: NA</p> <p>Medium: NA</p> <p>Facilitator: none</p>	<p>No intervention is an appropriate comparator</p>

(Continued)

	<p>nutrition education material</p> <p>Physical activity intervention: a graded physical activity plan, tailored to the participant's lifestyle and designed to enable them to achieve 20-30 min of aerobic activity at least once a week. The type of physical activity was tailored to the participant's interests, lifestyle and physical abilities. physical activities such as walking, cycling, swimming, dancing and playing golf were encouraged. Information leaflets about physical activity facilities available in Newcastle were provided as appropriate. A CiTY CARD (a scheme offering up to 80% discount on use of all public leisure facilities in the city) was offered to all participants</p> <p>Frequency: first 6 months 3 appointments at 2-weekly intervals, followed by 3 at monthly intervals. One after 9 months and 5 at 2-monthly intervals between 12 and 24 months</p> <p>No. of contacts: 12</p> <p>Group/Individual: individual</p> <p>Medium: in person</p> <p>Facilitator: dietitian and physiotherapist</p>

	<p>rie-deficit diet (not specific in nutritions) using culturally adapted and translated resources</p> <p>Physical activity intervention: weight loss through physical activity of at least 30 min daily brisk walking, using culturally adapted and translated resources</p> <p>Frequency: baseline, monthly for the first 3 months, then every 3 months</p> <p>No. of contacts: 15</p> <p>Group/Individual: both</p> <p>Medium: family</p> <p>Facilitator: dietician. In both the intervention and control groups family volunteers were asked to follow the advice given and to help the participants to follow it</p>		<p>vention: standard written and verbal advice on promotion of physical activity</p> <p>Frequency: baseline, then annually</p> <p>No. of contacts: 4</p> <p>Group/Individual: both</p> <p>Medium: family</p> <p>Facilitator: dietician. In both the intervention and control groups family volunteers were asked to follow the advice given and to help the participants to follow it</p>	
<p>SLIM 2003</p>	<p>I: Diet plus physical activity</p> <p>Dietary intervention: dietary recommendations were based on the Dutch guidelines for a healthy diet (about 55% energy from carbohydrates (maximum 15%-25% energy mono- and disaccharides); 30%-35% of energy from fat (\leq 10% energy saturated fatty acids; $<$ 33 mg/MJ cholesterol, maximal 300 mg a day); 10%-15% of energy from protein; Fibre more than 3 g/MJ a day</p> <p>A bodyweight loss of 5%-7% was the objective. If participants did not lose weight on this regimen during the first year, mild</p>	<p>Intensified diet and physical activity is an appropriate comparator</p>	<p>C: Standard recommendation</p> <p>Participants in the control group were given, oral and written information, about the beneficial effects of a healthy diet, weight loss and increased physical activity, whereas no individual advice or programmes were provided. No additional appointments were scheduled apart from annual follow-up visits</p> <p>Frequency: one (at baseline - thereafter annual follow-up visits with measurement of outcome variables, but no advice on diet or physical activity was given)</p>	<p>Standard diet and physical activity recommendation is an appropriate comparator</p>

(Continued)

	<p>energy restriction was prescribed during the second year. No very-low calorie diet or dietary products were used to encourage weight loss</p> <p>Physical activity intervention: participants were encouraged to increase their level of physical activity to at least 30 min of moderate physical activity a day for at least 5 days a week. Individual advice was given on how to increase daily physical activity (walking, cycling, swimming), and goals were set. Furthermore, participants were encouraged to participate in a physical activity programme, especially designed for the trial, including components of aerobic training and components of resistance training. Participants had free access to these training sessions, and were stimulated to participate for at least 1 hour a week. Participation in the physical activity sessions was recorded</p> <p>Frequency: The participants were seen at a baseline visit, after 4-6 weeks and thereafter every third month.</p> <p>No. of contacts: 14 visits during the planned three years of intervention. However, the duration of the trial was extended, so there have probably been more visits even though not stated.</p>		<p>No. of contacts: one Group/Individual: individual Medium: in person Facilitator: not reported</p>

WHAT'S NEW

Date	Event	Description
21 November 2017	New citation required and conclusions have changed	Update: diet plus physical activity reduces the risk of type 2 diabetes mellitus in people with impaired glucose tolerance. Data are lacking for the effect of diet plus physical activity for people with intermediate hyperglycaemia defined by other glycaemic variables
21 November 2017	New search has been performed	This review is an update of the review published in issue 3, 2008. Six trials of the original review were used for our review update. Also, we found six additional new trials and therefore established a database of 12 included trials

CONTRIBUTIONS OF AUTHORS

All protocol authors read and approved the final review update draft.

Bianca Hemmingsen (BH): review draft, acquisition of trial reports, trial selection, data extraction of all trials, data analysis, contact trial authors, data interpretation, GRADE assessment and writing of review drafts.

Gabriel Gimenez-Perez (GG): data extraction of all trials and review of drafts.

Didac Mauricio (DM): data interpretation and writing of review drafts.

Marta Roque i Figuls (MRF): data interpretation and writing of review drafts.

Maria-Inti Metzendorf (MIM): search strategy development, acquisition of trial reports and review of drafts.

Diet, physical activity or both for prevention or delay of type 2 diabetes mellitus and its associated complications in people at increased risk of developing type 2 diabetes mellitus (Review)

Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Bernd Richter (BR): review draft, search strategy development, acquisition of trial reports, trial selection, data analysis, data interpretation, GRADE assessment and writing of review drafts.

DECLARATIONS OF INTEREST

BH: none known.

GG: none known.

DM: has received consulting, educational activities or speaker's fees from Astra Zeneca, Eli Lilly, Ferrer, GlaxoSmithKline, Janssen, Menarini, Merck Sharp Dhome, Novartis, Novonordisk and Sanofi.

MRF: none known.

MIM: none known.

BR: none known.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

This is an update of a previous Cochrane Review ([Orozco 2008](#)). The original review included trials with other definitions of increased risk of type 2 diabetes mellitus. The current review only defines increased risk of type 2 diabetes mellitus with glycaemic measures. The original review included trials with a duration of one year or more. The current review includes trials with a duration of two years or more. The original review excluded trials not reporting the primary outcome. This review includes trials irrespective of the outcomes reported. The primary and secondary outcomes of the review have been changed, so the focus is on patient-important outcomes.

NOTES

We have based parts of the [Methods](#) and [Appendix 1](#) sections of this Cochrane Protocol on a standard template established by the CMED Group.
