31 catheter, wet wipes

32 **ABSTRACT:**

33 The study aimed to assess hygiene with wet wipes in bedridden patients with urinary  
34 catheters for catheter-associated urinary tract infection (CAUTI) prevention. CAUTI  
35 occurred in 16.5% of the control group compared to 5.9% of the intervention group (p=  
36 0.035). Hygiene with wet wipes can substitute for conventional hygiene for preventing  
37 CAUTI.

38 **INTRODUCTION**

39 Urinary tract infections (UTI) represent about 15%-20% of all healthcare-associated  
40 infections, and approximately 60% of these are associated with urinary catheters, which  
41 are used in up to 16% of inpatients (1). Up to 70% of UTIs are avoidable with the use of  
42 evidence-based prevention practices. (2)

43 Personal hygiene, including bathing, is a nursing activity related to quality of life and of  
44 medical care. The most widespread, well-described technique is conventional hygiene,  
45 which consists of washing the patient with a sponge or cloth, soap, and water from a  
46 basin. Over the last decade, waterless hygiene with the use of pre-saturated clothes has  
47 emerged as an alternative to conventional regimens (3).

48 Some authors sustain that hygiene with water can increase the risk of nosocomial  
49 infection, as the mechanical friction causes the shedding of cells containing  
50 microorganisms, which leads to contamination of the water. Similarly, tap water, toilets,  
51 sinks and basins can act as a reservoir for microorganisms and cause nosocomial  
52 infections (4, 5).

53 Given the importance of preventing UTIs and the scarcity of studies related to patient  
54 hygiene, this study aimed to assess hygiene with pre-saturated wipes versus conventional

hygiene in cardiac surgery bedridden patients for reducing catheter-associated urinary tract infections (CAUTI).

## **METHODS**

This open label randomized controlled trial took place in the Germans Trias i Pujol University Hospital between January 2019 and February 2020. This paper follows the CONSORT reporting guidelines for studies of non-pharmacological interventions(6).

### **Participants**

Patients undergoing cardiac surgery who were bedridden, had an indwelling urinary catheter, and provided signed informed consent were eligible to participate in the study.

Exclusion criteria were: missing records, patients admitted from other units with urinary catheters, patients with previous UTI in last 3 months, and language barrier. Patients were consecutively recruited until the sample size was reached. Upon enrollment, subjects were randomized to parallel groups (1:1) using a random numbers table. Patients were withdrawn from the study if they demonstrated hypersensitivity to any component of the hygiene protocol, transferred to other services, voluntarily dropped out, or died before completing the follow-up.

### **Intervention**

The control group received conventional patient hygiene with water and soap, while the experimental group received dry hygiene with wipes impregnated with soap and moisturizing lotion containing polyhexanide (Prontoderm wipes, B. Braun). Nursing professionals in the participating services received training on the hygiene protocol designed for the study. Urine samples were collected following hospital protocol and only in patients with clinically suspected infection.

78 **Ethical considerations**

79 The hospital's clinical ethics committee approved the study (code PI-18-173) and  
80 participants were asked to sign informed consent. Infection control nursing staff collected  
81 the data using a questionnaire with the study variables.

82 **Study variables**

83 The primary outcome was the occurrence of a CAUTI as defined by the Centers for  
84 Disease Control and Prevention (7)

85 Other variables were age, sex, comorbidity according to the Charlson Index, days of  
86 catheterization, skin integrity, microorganism in urine culture, antibiotic administration,  
87 treatment duration, and discharge outcome.

88 **Statistical analysis**

89 Assuming an alpha risk of 5%, allowing a 5% dropout rate, to provide 80% power, 100  
90 individuals were required in each group,

91 The accumulated incidence of CAUTI was calculated with 95% confidence intervals (CI),  
92 and groups were compared in univariable analyses using the chi-squared test or Fisher's  
93 exact test or the student's t test or Mann-Whitney U test . The study arm (experimental or  
94 control) was introduced into a multivariable logistic regression model adjusted for sex  
95 and days of catheterization. All analyses were performed using the SPSS statistical  
96 package (version 24). Two-tailed p values of less than 0.05 were considered significant.

98 A total of 212 patients were included in the study, of which 170 (85 per arm) were  
99 included in the analysis (Fig. 1). The only significant difference between groups was  
100 comorbidity: the Charlson index was higher in the control group (p=0.008).

101 The duration of catheterization ranged from 1-35 days. CAUTI was significantly more  
102 frequent in the control group (n=14 (16.5%), 95% CI 9.7% to 25.5% versus n=5 (5.9%,  
103 95% CI 2.2% to 12.5%) (p = 0.035). The incidence of CAUTI was higher among female  
104 participants (25.0%, 95% CI 13.9 % to 39.3 %) than male participants (6.4%, 95% CI  
105 3.1% to 11.8%; p = 0.002).

106 In the multivariable analysis (Table 1), CAUTI was independently associated with  
107 conventional hygiene (odds ratio [OR] 4.1 95% CI 1.3 to 12.7). In the 19 patients with  
108 CAUTI, 12 (60%) had infections caused by Enterobacterial (n = 9 controls versus n = 3  
109 experimental). *Pseudomonas* spp. were isolated in three cases, all in the control group.  
110 Four patients (20%) presented with polymicrobial cultures (75% in the control group).  
111 Nineteen patients (95%) received antibiotics during their hospital stay, with 58% of these  
112 continuing this treatment after discharge.

113 Most (94.1%) maintained skin integrity. More patients receiving conventional (7.1%)  
114 versus dry hygiene (3.5%), developed moisture-induced skin lesions, but the difference  
115 was not significant.

116 Regarding the discharge outcome, 89.1% of participants were discharged home, while  
117 4.1% died from non-infectious causes.

## 118 **DISCUSSION**

119 Our study provides evidence from an open label randomized controlled trial that water-  
120 based hygiene in bedridden patients with a urinary catheter is associated with a higher  
121 risk of CAUTI than hygiene with pre-saturated wipes.

122 A systematic review showed that waterless hygiene reduces the incidence of urinary  
123 infection(8) and recommended that healthcare centers consider eliminating patient  
124 bathing with basins. Other authors(9) found a reduction in UTIs when dry bathing  
125 practices were implemented, although most evidence is from pre-post studies comparing  
126 wet wipes impregnated with chlorhexidine to traditional soap, so the reduction could be  
127 due to the incorporation of the antiseptic.

128 In contrast, other authors (10) found insufficient evidence for the clinical efficacy of wet  
129 wipes with chlorhexidine and suggested the need for randomized clinical trials

130 In our study, CAUTI was independently associated with conventional water-based  
131 hygiene.

132 Most of the patients with CAUTI (60%) had an enterobacterial infection. The  
133 polymicrobial cultures, which were more frequent in the water-based hygiene arm, could  
134 reflect an excess of periurethral ascending contamination during washing with soap and  
135 water.

136 Groven et al (3) found that dry washing is associated with fewer skin lesions than  
137 conventional hygiene. We also observed that more patients receiving conventional versus  
138 dry hygiene developed skin lesions, although we failed to detect a statistically significant  
139 difference. One of the strengths of the current study is the inclusion of a randomly  
140 assigned control group and the incorporation of the change in hygiene technique with wet  
141 wipes as an isolated measure, rather than part of a multicomponent intervention. On the  
142 other hand, one limitation is that it was not double-blinded due to the type of intervention.  
143 Another possible limitation is that there were patients lost to follow-up in both study arms,  
144 possibly leading to bias due to the lack of information on these patients. Also, the study  
145 was limited to cardiac surgery patients and may not be generalizable to other populations.

65

146 In conclusion, in bedridden patients with a urinary catheter the use of pre-saturated wipes  
147 significantly reduced the incidence of CAUTI compared to conventional soap-and-water  
148 hygiene. Despite not containing an antiseptic, the wipes used in our study reduced the  
149 incidence of CAUTI, without disruption of skin integrity. Thus, performing skin hygiene  
150 pre-saturated wipes is a safe alternative to soap and water.

193 **Funding**

194 Funding/support: This work was supported by the “Trias Talents” Program of the  
195 Germans Trias i Pujol Research Institute and University Hospital.

196 There are no conflicts of interest.

197 **Acknowledgments**

198 We acknowledge the contributions of Ms. Àngels Barberà, A. Bayés i P. Ricart, and of  
199 all the nurses and physicians of the Cardiac Surgery and Intensive Care medical services  
200 at the Germans Trias i Pujol University Hospital.

201 The company B. Braun Medical donated the sanitary product after both parties had signed  
202 an agreement of no commitment.
