Long-Run In‡ation-Unemployment Dynamics: The Spanish Phillips Curve and Economic Policy

Marika Karanassou, Hector Sala, and Dennis J. Snower 5 November 2002

Abstract

This paper takes a new look at the long-run dynamics of in‡ation and unemployment in response to permanent changes in the growth rate of the money supply. We examine the Phillips curve from the perspective of what we call "frictional growth", i.e. the interaction between money growth and nominal frictions. After presenting theoretical models of this phenomenon, we construct an empirical model of the Spanish economy and, in this context, we evaluate the long-run in‡ation-unemployment tradeo¤ for Spain and examine how recent policy changes have a¤ected it.

Keywords: In‡ation-unemployment tradeo¤, Phillips curve, staggered wage contracts, nominal inertia, forward-looking expectations, monetary policy.

1. Introduction

This paper takes a new look at the long-run dynamics of in‡ation and unemployment in response to permanent changes in the growth rate of the money supply. We examine the Phillips curve from the perspective of what we call "frictional growth," i.e. the interaction between money growth and nominal frictions. After presenting theoretical models of this phenomenon, we construct an empirical model of the Spanish economy that aims to capture the essential features of the interplay between money growth and prolonged nominal adjustment processes. In this context, we evaluate the long-run in‡ation-unemployment tradeo¤ for Spain and examine how recent policy changes have a¤ected it.

The mainstream analysis of in‡ation and unemployment rests on the standard assumption that economic agents make their demand and supply decisions on the basis of real variables alone and thus, in the long-run labor market equilibrium, a change in the money supply has no real exects; it simply changes all nominal variables in proportion. It was on the basis of such money neutrality that Friedman (1968) and Phelps (1968) formulated the natural rate (or NAIRU) hypothesis, in which there is no permanent tradeox between in‡ation and unemployment.

We show that in the presence of money growth and time-contingent nominal contracts, this argument does not necessarily hold. Under plausible circumstances speci...ed below, changes in money growth may axect the unemployment rate and other real variables in the long run. This result enables our analysis to avoid a well-documented - but frequently ignored - counterfactual prediction of the NAIRU theory: Supposing that the NAIRU is reasonably stable through time - a commonly made assumption - in‡ation falls (rises) without limit when unemployment is high (low).

Another problem with the NAIRU theory is that, when combined with the rational expectations hypothesis, it implies that an inverse relation between intation and unemployment manifests itself primarily in response to unanticipated demand shocks. However, over the 1980s and 1990s many OECD countries had reasonably stable demand conditions (with a few notable exceptions), and nevertheless they frequently experienced large tuctuations in unemployment along-side relatively small changes in intation for periods as long as ...ve or ten years, or even longer. This evidence is di¢cult to reconcile with a stable NAIRU. Large and prolonged demand-side shocks were, in many countries, followed by prolonged changes in unemployment accompanied by only very slow declines in intation. Even longer-term intation-unemployment tradeoxs were found by Phillips (1958),

¹One may, of course, drop the assumption of a stable NAIRU and use the data to infer NAIRU movements, in accordance with the NAIRU theory. In that case, however, the NAIRU theory loses much of its predictive power.

Lipsey (1960) and others over the century preceding the late 1960s. Macroeconomic policy authorities often make monetary and ...scal policy decisions with prolonged in‡ation-unemployment tradeo¤s in mind.

This paper presents a model of the Phillips curve that avoids the counterfactual prediction that in ation falls (rises) without limit when unemployment is low (high), and it allows for the possibility of a long-run tradeo between in and unemployment.

Our analysis rests on three empirical regularities: (i) the growth rate of the money supply is nonzero, (ii) there is some nominal inertia, so that a current nominal variable is slow to adjust to money growth shocks, and (iii) unemployment is in‡uenced by the ratio of the nominal money supply to that nominal variable (such as the ratio of the money supply to the price level).

The ...rst regularity provides a reasonable time-series description of the money supply in most OECD countries. The second stylized fact is well-established empirically and has been rationalized theoretically.² In the presence of staggered time-contingent nominal contracts, current wages are a weighted average of their past and expected future values. A well-known result in the literature on the microfoundations of wage-price staggering³ is that when the rate of time discount is positive, the past is weighted more heavily than the future. It is in this sense that current prices and wages may be taken to be characterized by nominal inertia. The third regularity can take a variety of conventional forms, e.g. a change in the ratio of the money supply to the price level may a¤ect aggregate demand and thereby the unemployment rate.

In Section 2, we present three "toy models" of the macroeconomy, designed to highlight simply how frictional growth can lead to a long-run in‡ation unemployment tradeo¤. The equations of these models are ad hoc, short-hand summaries of plausible macro relations. In Section 3, we present a Phillips curve model with proper microfoundations. Section 4 contains an empirical model of the Spanish in‡ation-unemployment tradeo¤; we ...nd that this tradeo¤ is far from vertical in the long run. Section 5 evaluates how this tradeo¤ has been a¤ected by major shifts in economic policy. Finally, Section 6 concludes. Our analysis suggests that a signi...cant portion of the surge in the Spanish unemployment rate in the 1990s is due to contractionary monetary policy.

²See, for example, Taylor (1979)) on wage staggering, Calvo (1983), or Lindbeck and Snower (1999) on price precommitment with production lags. The literature on the exectiveness monetary policy under wage-price staggering has been surveyed by Clarida, Gali and Gertler (1999), Goodfriend and King (1997), Mankiw (2001), and others.

³For example, Ascari (2000), Ascari and Rankin (2002), Graham and Snower (2002), and Helpman and Leiderman (1990).

2. Toy Models

This section presents transparently simple macro models to describe two channels whereby permanent changes in money growth may have permanent exects on both intation and unemployment. We call these "toy models" since they are easy to play around with, being merely heuristic devices for introducing our ideas. They are speci...ed in an ad hoc way, as stripped-down pictures of how a long-run intation-unemployment tradeox may arise.

The ...rst model describes the "real money balance channel," i.e. an increase in money growth axects long-run real money balances and thereby the long-run unemployment rate. The second model considers the "real wage channel," whereby an increase in money growth axects long-run unemployment via the real wage and employment. And the third model considers both channels operating in tandem.

2.1. Model 1: The Real Money Balance Channel

In this model and the ones that follow, all variables - except the unemployment rate - are in logs. All uninteresting constants are ignored. Since we wish to focus on the long-run in‡ation-unemployment tradeo¤ and since movements along this tradeo¤ arise from permanent changes in money growth, let money growth have a unit root:

$$\Phi_{t} = \mathbf{1}_{t_{i}, 1} + \mathbf{1}_{t'};$$
 (2.1)

where M_t is the (log of the) money supply and " $_t$ is a white-noise error term. The current price level depends on the past price level and the money supply:

$$P_t = aP_{t_i 1} + (1_i a) M_t;$$
 (2.2)

where the "price sluggishness parameter" a is a constant, 0 < a < 1. This is the only substantive ad hoc simpli...cation that this model makes in describing frictional growth. As noted, the microfoundations literature on price staggering indicates that the current price level is a weighted average of past and expected future price levels, with the past weighted more heavily than the future, under time discounting. Equation (2.2) provides a simpli...ed picture of this source of price inertia and it thereby clari...es the mechanism whereby frictional growth generates a downward-sloping long-run Phillips curve. (We will consider a microfounded model in Section 3.)

Aggregate product demand depends on real money balances:

$$Q_t^D = (M_{t j} P_t):$$
 (2.3)

The aggregate production function is

$$Q_t^S = \frac{3}{4}N_t;$$
 (2.4)

where ¾ is a positive constant⁴. The labor supply is constant:

$$L_{t} = L; (2.5)$$

so that the unemployment rate (not in logs) can be approximated as

$$u_t = L_i N_t: (2.6)$$

Observe that money illusion is absent in system (2.1)-(2.6): if all nominal variables are changed in equal proportion, then the associated real variables remain unchanged. Nevertheless, it can be shown that there is a long-run in‡ation-unemployment tradeo¤ and that changes in money growth can move the economy along this tradeo¤.

De...ning the intation rate as $\%_t$ $^{\prime}$ $P_{t\,i}$ $P_{t\,i}$ and taking the ...rst dixerence of the price equation (2.2), we obtain

$$y_t = ay_{t_i 1} + (1_i a)_t^1$$
: (2.7)

It is straightforward to show that, in this context, the long-run in‡ation rate is equal to the long-run money growth rate: $\%^{LR}_t = \%^{LR}_t$ (which bears the time subscript since money growth is a random walk).⁵ Furthermore, long-run real money balances depend on long-run money growth rate:⁶

$$(M_{t i} P_t)^{LR} = \frac{a}{1_{i} a} {}^{1_{k}}_{t}^{LR}$$
: (2.8)

$$V_{t}^{LR} = {}^{1}_{t}^{LR}_{i}_{i} \frac{a}{1_{i} a} (CV_{t})^{LR}$$
 (F1)

Now take the ...rst di¤erence of (2.7), $\mathfrak{C} \mathfrak{A}_t = a \mathfrak{C} \mathfrak{A}_{t_i \ 1} + (1_i \ a) \mathfrak{C}_t^1$, and note that the long-run solution this equation is given by its unconditional expectation: $(\mathfrak{C} \mathfrak{A}_t)^{LR} \mathcal{E}(\mathfrak{C} \mathfrak{A}_t)$. Taking expectations on both sides of the previous equation, we obtain

$$E(\Phi V_t) = 0$$
; or $(\Phi V_t)^{LR} = 0$; (F2)

since $E(\mathfrak{C}_{t_i}) = E(\mathfrak{C}_{t_{i-1}})$; due to stationarity, and $E(\mathfrak{C}_{t_i}) = 0$; by equation (2.1), where E is the unconditional expectations operator.

Substitution of (F2) into (F1) yields $\frac{LR}{t} = \frac{LR}{t}$:

 $^{^4}$ % = 1 under constant returns to labor, and % is less (greater) than unity under diminishing (increasing) returns.

 $^{^5}$ To see this, rewrite equation (2.7) as $\frac{1}{1}$ a $\frac{1}{1}$ a $\frac{1}{1}$ $\frac{1}{1}$ a $\frac{1}{1}$ $\frac{1}{1}$ Thus, given structural stability, the long-run relationship between the in‡ation rate and the growth rate of money supply is

⁶To see this, note that equation (2.2) may be rewritten as (1 $_i$ a) $M_t = (1 _i$ a) $P_t + a 1_t$, and recall that $1_t^{LR} = 1_t^{LR}$.

Consequently, by (2.3)-(2.6) and (2.8), we obtain a long-run (steady-state) relation between unemployment and in ation:

$$\mathcal{H}_{t}^{LR} = \mathcal{H}_{a} \frac{\mathbf{1}_{i} a}{a} \mathbf{1}_{i} L_{i} u_{t}^{LR}$$

$$(2.9)$$

The long-run Phillips curve is ‡atter,

- ² the greater is the price sluggishness parameter a and
- ² the greater is the curvature of the production function (i.e. the smaller ¾).

It is straightforward to see the intuition underlying the downward slope of the Phillips curve. When the money supply grows, the price level chases after a moving target. But since the money supply keeps on increasing, the price adjustments never work themselves out entirely. By the time the current price level has begun to respond to the current increase in the money supply, the money supply increases again, prompting a new round of price adjustments. The greater is money growth, the greater will be the diæerence between the target and actual price levels (ceteris paribus). Thus a permanent increase in money growth not only increases long-run in‡ation, but also raises real money balances and thereby reduces unemployment in the long run. On this account, there is a long-run tradeoæ between in‡ation and unemployment.

2.2. Model 2: The Real Wage Channel

Our second macro model deals with the real wage channel. To illustrate this channel as simply as possible, suppose that the price level adjusts instantaneously to the money supply:

$$P_t = M_t; (2.10)$$

whereas the nominal wage is sluggish, depending on its past value and the current money supply:

$$W_t = bW_{t_{i-1}} + (1_{i-1}b)M_t;$$
 (2.11)

where b, the "wage sluggishness parameter," is a constant, 0 < b < 1.

As in the previous section, the growth rate of money supply has a unit root, as given by equation (2.1). In this context, an unexpected change in money growth

leads to a change in the real wage. Employment, in turn, depends on the real wage:

$$N_t = c_0 i c_1 (W_t i P_t);$$
 (2.12)

where $W_{t\ i}$ P_{t} is the log of the real wage; and the labor demand curve is derived from the production function (2.4), so that $c_{0} = \frac{\log \frac{1}{4}}{1_{i}}$ and $c_{1} = \frac{\frac{1}{4}}{\frac{1}{4}i}$: As in the previous section, the labor supply is constant (equation (2.5)), and the unemployment rate is given by equation (2.6).

De...ning the rate of wage in \ddagger ation as $o_t = W_{t,i} W_{t,i-1}$, and taking the ...rst dixerence of the wage equation (2.11), we obtain

$$o_t = b_{t_i 1} + (1_i b)_{t_i}^1;$$
 (2.13)

Thus the long-run rate of wage in‡ation is ${}^{\circ}_{t}^{LR} = \%_{t}^{LR}$. The long-run real wage depends on the long-run money growth rate:⁷

$$(W_{t j} P_t)^{LR} = \frac{j b}{1 j b} 1_t^{LR}$$
: (2.14)

The greater the long-run growth rate of the money supply, the lower is the corresponding long-run real wage. Thus greater is employment and the lower is unemployment in the long run.

To derive the associated long-run Phillips curve, observe that $^1_t = \frac{1}{2}$ (by equation (2.10), recall that $^{\circ LR}_t = \frac{1}{2}$, and use equations (2.12), (2.6) and (2.14) to obtain:

$$\mathcal{H}_{t}^{LR} = \frac{1_{i} b_{i}}{c_{1}b} L_{i} u_{t}^{LR}$$

$$(2.15)$$

This long-run Phillips curve is ‡atter,

- 2 the greater is the wage sluggishness parameter b and
- 2 the greater is the slope of the labor demand curve c_{1} .

Once again, the intuition is clear. When the nominal wage is subject to more inertia than the price level then, in the presence of money growth, the wage chases after its moving wage target more slowly than the price chases after its moving price target. The faster the money supply grows, the more the price level rises relative to the nominal wage. Thus the real wage falls, labor demand rises, and unemployment falls.

⁷To see this, rewrite the wage equation as $(1_i b) P_t = (1_i b) W_t + b_t^o$.

An obvious de...ciency of the real wage channel is that, on its own, it implies that real wages always move counter-cyclically, and this prediction is counterfactual. The evidence suggests that although real wages are counter-cyclical in some countries during some time periods, there are plenty of occasions in which they are pro-cyclical and acyclical. In practice, however, the real wage channel is unlikely to operate in isolation. When it is combined with the real money balance channel, for instance, the resulting real wages are no longer necessarily counter-cyclical, as shown below.⁸ Furthermore, it is well to keep in mind that, in practice, the real wage moves in response to many determinants, of which the money supply is only one. Thus an inverse relation between the real wage and money growth may coexist with pro-cyclical real wage behavior.

2.3. Model 3: Both Channels

Our ...nal macro model is concerned with the interplay between the two channels above, which turns out to have interesting implications for the long-run in‡ation-unemployment tradeo¤. For this purpose, we consider a model in which there is lagged adjustment in both wages and prices. Speci...cally, let the money growth rate be given by equation (2.1), the price equation by (2.2), the wage equation by (2.11), labor supply by (2.5), and unemployment by (2.6):

where the price- and wage-sluggishness parameters satisfy 0 < a; b < 1:

Furthermore, to enable both channels to operate, we extend the labor demand equation to allow employment to depend on both the real wage ($W_t \cap W_t$) and real money balances (M_t):

$$N_t = c_0 i c_1 w_t + \frac{1}{3/4} (M_t i P_t);$$
 (2.16)

where the parameters c_0 ; c_1 and $\frac{3}{4}$ are positive.

⁸The reason is that the impulse-response function of the real wage to money growth shocks need not be monotonic.

⁹The underlying assumption now is that changes in product demand (initiated by changes in real money balances) can intuence the position of the labor demand function. Lindbeck and Snower (1994), for example, describe various microfounded channels whereby product demand changes can axect the labor demand function in the long run.

To derive the in‡ation-unemployment tradeo¤ in this setting, we ...rst obtain the stochastic process for the real wage by subtracting the price equation (2.2) from the wage equation (2.11):

$$W_{t} = (a + b) W_{t_{i} 1 j} abW_{t_{i} 2 j} (b_{j} a)^{1}_{t};$$
 (2.17)

Next, note that the price equation (2.2) can be rewritten in terms of the real money balances:¹⁰

$$(M_{t,i} P_t) = a (M_{t,i,1} P_{t,i,1}) + a_t^{1}$$
: (2.18)

Substitute equation (2.17) and (2.18) into the labor demand equation (2.16) to ...nd how employment depends on its past values and money growth:

$$N_{t} = (a + b) N_{t_{i} 1 j} abN_{t_{i} 2} + c_{1} (b_{j} a) + \frac{a}{3/4} (1_{j} b)^{1}_{t} + \frac{ab}{3/4} "_{t}:$$
 (2.19)

Finally, by manipulation of equations (2.6) and (2.19) gives the following stochastic process for the unemployment rate:

$$u_{t} = (a + b) u_{t_{i} 1 j} abu_{t_{i} 2} + (1 j a) (1 j b) L_{j} c_{1} (b j a) + \frac{a}{3/4} (1 j b)^{-1}_{t j} \frac{ab}{3/4}"_{t};$$
(2.20)

Thus the long-run unemployment rate is

$$u_{t}^{LR} = L_{i} \frac{\sqrt[3]{c_{1}(b_{i} a) + a(1_{i} b)}}{\sqrt[3]{(1_{i} a)(1_{i} b)}} \sqrt[3]{LR}; \qquad (2.21)$$

and the associated long-run Phillips curve is 11

$$\mathcal{H}_{t}^{LR} = \frac{\sqrt[3]{(1_{i} \ a)(1_{i} \ b)}}{\sqrt[3]{(1_{i} \ b) + a(1_{i} \ b)}} \, \mathbf{i}_{L_{i}} \, \mathbf{u}_{t}^{LR} \,$$
(2.22)

It can be shown that

$$\begin{split} P_t = a P_{t_i \ 1} + (1_i \ a) \, M_t \,) \ (M_{t \ i} \ P_t) = a M_{t \ i} \ a P_{t_i \ 1} \\ (M_{t \ i} \ P_t) = a M_{t \ i} \ a P_{t_i \ 1} + a M_{t_i \ 1} \, i \ a M_{t_i \ 1} = a \, (M_{t_i \ 1} \, i \ P_{t_i \ 1}) + a^1_t ; \end{split}$$

¹⁰By equation (2.2),

^{^11}Note that, in the context of this model, b > a (more wage sluggishness than price sluggishness) is a su⊄cient condition for the Phillips curve to be downward-sloping. In this case, the money balance and real wage channels reinforce one another: an increase in money growth not only raises real money balances, but it also reduces the real wage (since the nominal wage responds less than the price level). But if b < a, the Phillips curve is still downward-sloping provided that $\frac{a(1_i b)}{(a_i b)}$.

- ² The greater the wage sluggishness parameter b, the ‡atter is the long-run Phillips curve.¹² The more sluggish is the nominal wage, the more will a given change in money growth reduce the real wage and thereby raise employment (ceteris paribus). Thus the greater will be the reduction in unemployment relative to the rise in in‡ation.
- ² The greater is the price sluggishness parameter a, the ‡atter is the long-run Phillips curve, provided that the real money balance channel dominates the real wage channel, i.e. when $1=\frac{3}{4} > c_1$ in the employment equation (2.16).¹³ The more sluggish is the price level, the more will a given change in money growth raise real money balances as well as the real wage (ceteris paribus). Then, if the money balance channel dominates the real wage channel, the greater will be the rise in employment, and therefore the greater the fall in unemployment relative to the increase in in‡ation¹⁴.
- ² If the money balance channel dominates the real wage channel, then the wage sluggishness and price sluggishness are complementary in their in tuence in making the long-run Phillips curve ‡atter. In particular, 15

$$\frac{@^{2} \text{w}}{@b@a} = \frac{2 \frac{3}{4} c_{1} (1_{i} \ a) (1_{i} \ b) (1_{i} \ \frac{3}{4} c_{1})}{\left[\frac{3}{4} c_{1} (b_{i} \ a) + a (1_{i} \ b)\right]^{3}} > 0 \text{ if } \frac{3}{4} c_{1} < 1:$$

3. A Microfounded Model

Whereas the macro models above convey our intuitions as simply as possible, this section develops a model of the real wage channel that can be given ...rm microfoundations.¹⁶ We consider a labor market containing a ...xed number of identical ...rms with monopoly power in the product market. The i'th ...rm has a production function of the form

$$q_{i;t}^{S} = A n_{i;t}^{4};$$
 (3.1)

^{(2002).}

where $q_{i;t}^{S}$ is output supplied, $n_{i;t}$ is employment, A and $\mbox{\em 3}$ are positive constants, and $0 < \frac{3}{4} < 1$. Each ...rm faces a product demand function of the form

$$q_{i;t}^{D} = \frac{\mu_{p_{i;t}}}{p_{t}} \frac{q_{t}^{D}}{f}; \qquad (3.2)$$

where q_t^{D} stands for aggregate product demand (to be speci...ed below), f is the number of ...rms, p_{i:t} is the price charged by ...rm i, p_t is the aggregate price level, and f is the price elasticity of product demand (a positive constant).

The ...rm's pro...t-maximizing employment decision sets its marginal revenue $(MR_{i;t} = p_{i;t} \ 1_i \ \stackrel{!}{\overset{!}{\cdot}} \) \ \text{equal to its marginal cost} \ (MC_{i;t} = !_{i;t} \ \stackrel{@n_{i;t}}{\overset{@n_{i;t}}{\overset{!}{\cdot}}} \ = \frac{!_{i;t}}{\frac{3}{4}A} n_{i;t}^{1_i} \stackrel{\%}{\overset{\%}{\cdot}}$ where ! $_{i;t}$ is the wage paid by the ...rm). Thus the ...rm's labor demand is given by $\frac{!}{^{1}_{4A}}$ $n_{i;t}^{1_{i}}$ $^{1_{i}}$ $^{1_{i}}$ $^{1_{i}}$ $^{1_{i}}$: In the labor market equilibrium, $p_{i;t}=p_{t}$ and $!_{i;t}=!_{t}$, due to symmetry. Aggregating all the individual ...rms' labor demand functions and taking logarithms, so that $N_t = \log(fn_{i:t})$, we obtain the following aggregate employment equation:

$$N_t = a_i a_w (W_t P_t);$$
 (3.3)

where $W_t = log(!_t)$, $P_t = log(p_t)$; $a = \frac{log(1_i \cdot !_j) + log(\%A) + (1_i \cdot \%) log f}{1_i \cdot \%}$, and $a_w = \frac{1}{1_i \cdot \%}$. As above, the labor supply is constant (equation (2.5). Our aggregate price

equation is equivalent to the aggregate employment equation under product market clearing. The product market clearing condition is $fAn_{i;t}^{4}=q_{t}^{D}$: Taking logs, de…ning $h=\log{(Af^{1_{i}})^{4}}$ and $Q_{t}^{D}=\log{(q_{t}^{D})^{4}}$, and rearranging gives: $N_{t}=100$ $\frac{1}{4}Q_t^D$ i $\frac{h}{4}$: Substituting this equation into the aggregate employment equation (3.3), we obtain the following price equation: 17

$$P_{t} = W_{t} + \frac{1}{2}Q_{t}^{D} i^{-}; (3.4)$$

where $\frac{1}{4} = \frac{1}{4} = \frac{1}{4} = \frac{1}{4}$; and $\frac{1}{4} = \frac{1}{4} = \frac{1$ Along the standard lines, we suppose that there are two wage contracts, evenly staggered, each lasting for two periods. Let -t be the (log of the) contract wage negotiated at the beginning of period t for periods t and t + 1: Taylor's staggered contract equation is

$$-_{t} = ^{\otimes} -_{t_{i} 1} + (1_{i} ^{\otimes}) E_{t-t+1} + ^{\circ} (c + ^{\otimes}_{i t} + (1_{i} ^{\otimes}) E_{t i t+1}) + ^{3}_{t};$$
 (3.5)

the expectations operator, denoting the expectation conditional on information

¹⁷To see this, rewrite the employment equation as $P_t = \frac{a}{a_w} + W_t + \frac{1}{a_w} N_t$:

available at time t. We assume that agents do not have information about 3 when they set their wage contracts at time t; so $E_t{}^3{}_t=0$: The variable $_i$ t is what Taylor calls "excess demand," speci…ed as actual output (Q_t^s) less full-employment output (in logs). By the production function (3.1), full-employment output is $Q_t^s={}^3\!\!\!/ L+h$; or $Q_t={}^3\!\!\!/ L+h$ since we assume that the product market clears. Thus excess demand (in logs) is

$$j_t = Q_t j \ ^{3}L j \ h: \tag{3.6}$$

The microfoundations of the contract equation under time discounting 18 - which, for brevity, we need not summarize here - indicate that the coe $\mbox{\-Cient}$ $^{\mbox{\-Re}}$ is a discounting parameter equal to $\frac{1}{1+\pm}$, where \pm is the discount factor. 19 $^{\circ}$ is a "demand sensitivity parameter" (describing how strongly wages are in‡uenced by demand), and c as a "cost-push parameter" (describing the upward pressure on wages in the absence of excess demand). Since $\pm<1$, we infer that $\mbox{\-Re}>1=2$, i.e. discounting gives rise to an asymmetry in wage determination: the current wage $-_t$ is a ected more strongly by the past wage $-_{t_i}$ 1 than the future expected wage E_{t^-t+1} .

The average wage is

$$W_{t} = \frac{1}{2} \left(-_{t} + -_{t_{i}} \right) : \tag{3.7}$$

Aggregate demand ${}^{\mathbf{i}}Q_{t}^{D}{}^{\mathbf{c}}$ is depends on real money balances

$$Q_t^D = M_t i P_t; (3.8)$$

where M_t is the log of the money supply. (For brevity, again, we omit the standard microfoundations.)

Finally, money growth follows a random walk (equation (2.1)). This implies that the contract wage may be expressed in terms of its own lagged value and the money supply:²⁰

$$-_{t} = (1_{i} _{1}) (1 + \frac{1}{2}) (c_{i} _{1} _{2} L_{i} _{1} _{1}) + (1_{i} _{1})^{-} + (1_{i} _{1})^{-} + (1_{i} _{2})^{-} + (1_{i} _{2})^{-}$$

$$Q_{t} = \frac{\mu}{1 + \frac{1}{1 + \frac{1}{2}}} M_{t i} \frac{1}{2(1 + \frac{1}{2})} (-_{t} + -_{t_{i} 1}) + \frac{-}{1 + \frac{1}{2}}$$

¹⁸Ascari (2000), Ascari and Rankin (2002), Graham and Snower (2002), Helpman and Leiderman (1990), and others. See also Huang and Liu (2002).

¹⁹Since this result is derived by linearizing a wage equation around a steady state of zero money growth, the theoretical analysis of this section applies only to money growth rates that are su⊄ciently low.

²⁰To see this, substitute the price equation (3.4) and the wage equation (3.7) into the aggregate demand equation (3.8):

where $_{3,1;2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_3}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2}}{2A_3}$; and $_{3,2} = \frac{A_2 \cdot P_{A_2^2 i \cdot 4A_1 A_2$

Substituting (3.9) into (3.7), we obtain the aggregate nominal wage dynamics equation:

$$W_{t} = \begin{pmatrix} 1_{i} & 1_{1} \end{pmatrix} \begin{pmatrix} 1 + \frac{1}{2} \end{pmatrix} \begin{pmatrix} 1 + \frac{1}{2} \end{pmatrix} \begin{pmatrix} 1 + \frac{1}{2} \end{pmatrix} \begin{pmatrix} 1_{i} & \frac{1}{2} \end{pmatrix} \begin{pmatrix} 1_{i} & 1_{1} \end{pmatrix} \begin{pmatrix} 1_{i$$

Note that in the long-run, wage in ation is equal to the money growth rate: $\mathbb{C}W_t^{LR} = {}^{1}L^{R}:^{21}$

To derive the dynamics of the real wage, we ...rst express price in terms of wages and money (i.e., insert (3.8) into (3.4)):

$$P_{t} = (1_{j} \mu) W_{t} + \mu M_{t j} (1_{j} \mu)^{-}; \qquad (3.11)$$

where $\mu=\frac{1}{1+1/2}$: Observe that equation (3.10) and (3.11) imply that in the long-run, in‡ation is equal to the money growth: $4^{LR}_t = 1^{LR}_t$: Substituting (3.10) into

Next, substitute this equation and (3.6) into the contract equation (3.5):

Apply the expectations operator E_t on the above equation, recall that $E_t^3_t = 0$; collect terms together, so that

$$\begin{split} \dot{A}_1 E_{t^-t_i \ 1} + \dot{A}_2 E_{t^-t} + \dot{A}_3 E_{t^-t+1} &= i \ ^\circ (1 + 1) \ (c_i \ ^3\!\!/ L_i \ h)_i \ ^{\circ -} \\ & i \ ^\circ [^\circledast E_t M_t + (1_i \ ^\circledast) E_t M_{t+1}]; \end{split}$$

where
$$\acute{A}_1={}^{\circledR}i_1+{}^{\Lsh}i_1$$
; $\acute{}_2$; $\acute{A}_2=i_1+{}^{\Lsh}i_2+{}^{\circlearrowleft}i_3$; $\acute{A}_3=(1_i{}^{\circledR})^i_1+{}^{\Lsh}i_1$; $\overset{\circ}{}_2$: Assuming that the contract wage $-_t$ is dynamically stable, the rational expectations solution

of the previous equation is given by (3.9).

²¹The wage intation equation is given by the ...rst dixerence of (3.10):

where B, Φ are the backshift and ...rst diæerence operators, respectively. The long-run solution of the above equation is obtained by setting the error terms $(^3_t;"_t)$ equal to zero and the backshift operator B equal to unity.

(3.11), we ...nd the real wage dynamics equation:²²

$$W_{t | i} P_{t} = (1_{i - 1}) (c_{i} ^{3}4L_{i} h + ^{-}) + _{s1} (W_{t_{i} 1 | i} P_{t_{i} 1})_{i} (1_{i - 1}) \frac{\mu_{2^{\circ} i} 1^{-1}}{\circ} 1_{t}$$

$$i \frac{\mu}{2} (1_{i - 1}) "_{t} + \frac{\mu}{2} i_{3_{t}} + 3_{t_{i} 1} : \qquad (3.12)$$

Inserting this real wage into the employment equation (3.3) and the unemployment rate (2.6), we derive the unemployment dynamics equation:

$$u_{t} = (1_{i}_{3})(1_{i}) \left(\frac{a_{w}}{4} \right) L_{1} + (1_{i}_{3}) \left[a_{w}(c + i_{i}) \right] + a_{w} \frac{\mu_{i}}{2} + a_{w} \frac{\mu_{i}}{2} + a_{w} \frac{\mu_{i}}{2} \right]$$

$$i_{t} a_{w}(1_{i}_{3}) \frac{\mu_{i}}{2} + a_{w} \frac{\mu_{i}}{2} \right]$$

$$(3.13)$$

Thus the long-run unemployment rate is

$$u_{t}^{LR} = (1_{i} a_{w}^{3}) L + a_{w} (c + _{i} h)_{i} a_{i} a_{w} \frac{\mu_{2^{\otimes} i}^{1} 1_{t}^{LR}}{\sigma_{t}^{1}}$$
(3.14)

Given that $\mathcal{H}_t^{LR} = \mathcal{H}_t^{LR}$; the long-run Phillips curve is²³

$$\mathcal{H}_{t}^{LR} = i \frac{(1_{i} \frac{3}{4})}{(2^{\otimes} i 1)} u_{t}^{LR} + \frac{\mu}{2^{\otimes} i 1} c + (1_{i} 2^{3}) L + \frac{h}{\frac{3}{4}}$$
(3.15)

Note that, since $\frac{1}{2} < ^{\circledR} < 1$; there is a tradeo¤ between in‡ation and unemployment both in the short-run and the long-run.²⁴

As we can see, the long-run Phillips curve is ‡atter,

$$\begin{split} W_{t\;i}\;\;P_{t} &= (1_{\;i}\;\; _{_{_{_{_{_{_{_{_{_{1}}}}}}}}}1)\,(c_{\;i}\;\; ^{3}\!\!\!/L_{\;i}\;\;h+\bar{}^{\;-}) + _{_{_{_{_{_{_{_{_{_{_{1}}}}}}}}1}\,(W_{t_{i}\;\;1}\;\;P_{t_{i}\;\;1}) \\ i\;\mu\;\;\frac{1}{2}\,(1+_{_{_{_{_{_{_{_{_{_{1}}}}}}}}1)\,i\;\;\;(1_{\;i}\;\;_{_{_{_{_{_{_{_{_{1}}}}}}}1}})^{\;\;1}_{t\;i}\;\;\frac{\mu}{2}\;\;(1_{\;i}\;\;_{_{_{_{_{_{_{_{_{1}}}}}}}1}})\,"_{t}\;+\frac{\mu}{2}\,i^{\;3}_{t\;i}\;+^{\;3}_{t_{i}\;1}\;: \end{split}$$

It can be shown that $\mu = \frac{\mathbf{f}}{2} (1 + \mathbf{j})_{i} = (1$

$$\text{$^{LR}_{t}$} = \text{$_{i}$} \; \frac{\text{$^{\circ}$}}{a_{w} \, (2^{\circledR} \, \text{$_{i}$} \; 1)} u_{t}^{LR} + \frac{\text{$^{\circ}$} \, [(1 \, \text{$_{i}$} \; a_{w} \, \text{$^{\prime}\!\!\!/}_{4}) \, L + a_{w} \, (c + \, \text{$^{-}$} \, \text{$_{i}$} \; h) \, \text{$_{i}$} \; a]}{a_{w} \, (2^{\circledR} \, \text{$_{i}$} \; 1)} :$$

Recalling that $a_w = \frac{1}{1_i \frac{\pi}{4}}$ and $\bar{a}_w = \frac{a}{a_w} + \frac{h}{\frac{\pi}{4a_w}}$, substituting these expressions into the above equation, and through some algebraic manipulation, we obtain the long-run Phillips curve (3.15). ²⁴Of course, this occurs under diminishing returns to labor (0 < \frac{\pi}{4} < 1): Increasing returns to labor will produce an upward-sloping Phillips curve.

²²Equations (3.10) and (3.11) imply

- ² the greater is the real interest rate, and thus the more backward-looking is the wage contract (i.e. the greater is [®]), and
- 2 the less sensitive is the contract wage to aggregate demand (i.e. the lower is °)
- ² the greater is ¾, i.e., the less diminishing are the returns to labor.

Intuitively, when ® or ° falls, the average nominal wage - and therefore the price level - responds more slowly to an increase in money growth. Thus a given increase in money growth leads to a larger increase in the real wage, a larger rise in labor demand, and thus a a larger decline in unemployment.

It is easy to see that, for parameter values common in the literature, the long-run Phillips curve is far from vertical. We can express the slope of this Phillips curve as $i^{\frac{\circ(2+r)(1_i - 3)}{r}}$, where r is the real discount rate ($\pm = \frac{1}{1+r}$). When $\frac{3}{4} = 0.75$ and $\frac{\circ}{100}$ is 0.1,25 the slope is -2.53 for a real discount rate of 2 percent, and it is -1.03 for a real discount rate of 5 percent.

It is important to emphasize, however, that the real wage channel is unlikely to be operative in isolation. Indeed, the theoretical model above is far too narrowly focused to generate reliable measures of the in‡ation-unemployment tradeo¤. We can gain a broader perspective through an estimated macro model, to which we now turn.

4. Empirical implementation

This section applies our analysis of the in‡ation-unemployment tradeo¤ to an empirical investigation of the Spanish economy. Spain is a particularly interesting country for such an analysis, since it has witnessed major institutional and policy changes over the sample period - the transition to democracy, the advent of unionized collective wage bargaining, several waves of labor market reforms, entry into the EEC, and central bank independence, to name a few. In our empirical analysis below, we attempt a rough assessment of how such changes in‡uenced the Phillips curve. Due to data limitations, however, our results should be seen as merely a tentative, ...rst step towards a full-blown empirical reappraisal of the Phillips curve on the basis of frictional growth.

²⁵There is broad disagreement about the appropriate value of °. Empirical estimates range from around 0.5 to 0.1 (see, for example, Taylor (1980b) and Sachs (1980)), whereas calibration of microfounded models often assigns values between 0.2 and 1 (see, for example, Huang and Liu (2002)).

²⁶Appendix A presents a short account of these major events.

We ...rst present estimates of a structural model of the Spanish economy, in which context the long-run in‡ation-unemployment tradeo¤ can be derived. We then investigate how various important institutional and policy changes in Spain over the past few decades may have a¤ected this tradeo¤.

4.1. The Empirical Model

Modeling the in‡ation-unemployment tradeo¤ involves some hard choices. Since our theory rests on lagged labor market responses to money growth, we can gain a broad macro perspective on the underlying propagation mechanisms by considering a wide set of lagged responses in employment, wage setting, and labor force participation activities. Moreover, since our theory is concerned with the way in which wage and price adjustments in‡uence real economic activities, our empirical model contains a nominal wage equation and a price equation, as well as careful structural speci...cations of employment and labor force participation equations. Thus we assess the long-run in‡ation-unemployment tradeo¤ by estimating a multi-equation system, rather than the more common single-equation, reduced-form Phillips curve. Our analysis indicates that the interactions among our various adjustment processes play a signi...cant role in determining the long-run in‡ation-unemployment tradeo¤.

Since Spain has witnessed several profound policy changes over the past three decades (see Appendix A for a discussion) we attempt to capture shifts of policy regimes through the use of dummy variables in our empirical model. This is a transparently rough procedure, but di¢cult to re…ne in macroestimation.

Finally, we endeavor to take seriously the common ...nding that productivity growth and capital accumulation play an important role in determining employment and unemployment. Thus productivity and the capital stock are not exogenous variables in our analysis;²⁸ rather, our empirical model includes an aggregate production function, relating output to employment and capital, and a capital stock equation, containing further lagged endogenous variables.

This leaves us with a sizable econometric model, comprising seven equations: employment, labor force, wage, price, and capital stock equations, as well as a production function and the de...nition of the unemployment rate. This leaves us with

²⁷Empirical macroeconomic models of the Spanish labor market have tended to focus on employment rather than the labor force. A signi...cant exception is De Lamo and Dolado (1993).

²⁸ Just as the costs of buying and selling (or depreciating) capital make investment decisions intertemporal, so the costs of hiring, training and ...ring labor make employment decisions intertemporal as well. Thus, we view ...rms as making their employment, investment, and production decisions together, with reference to broadly similar time horizons. On this account it appears inadvisable to hold the capital stock and productivity constant when estimating an employment equation.

fewer degrees of freedom than we might ideally wish for, but more than enough to identify well-speci...ed structural equations. There is a well-known tradeo¤ between structural detail and the power of econometric tests and our empirical model favors the structural detail.

Our theoretical analysis and attention to policy changes have led us to chose structural modeling rather than the VAR approach.²⁹ The structural models are able to give more attention to policy variables and other exogenous variables outside the labor market, which tend not to be included in the VAR models.

Our estimation uses OECD annual data over a sample from 1966 to 1998.³⁰ The de...nitions of variables are given in Table 1.

Table 1: De...nitions of variables money supply (M3) employment price level (GDP de‡ator) labor supply nominal wages unemployment rate real wage (Wt i Pt) working age population real money balances (M_{t i} P_t) indirect taxes as a % of GDP m_t ¿τ real labor productivity real social security bene...ts μ_t real GDP import price level Уt competitiveness (import price GDP detator) k_t real capital stock t lingar time trend $\frac{1}{2}$ 1; for t = 19711; for t = j; :::; 1998; j > 19710; otherwise 0; otherwise

All variables are in logs except for the unemployment rate u_t and the tax rate i_t : For any variable x_t in our data set, slope dummies are given by $x_t^j = d_t^j x_t$:

We ...rst estimated each of the equations in our model using the autoregressive distributed lag (ARDL) approach to cointegration analysis,³¹ and used the Akaike and Schwarz information criteria to determine the optimal lag-length. The selected speci...cations are dynamically stable (i.e., the roots of their autoregressive polynomia lie outside the unit circle), and pass the standard diagnostic tests

²⁹Both approaches have received ample attention in empirical labor market studies. Following Blanchard and Quah (1989), a number of the recent studies devoted to the Spanish labor market analysis opt for the structural VAR approach. For instance, Dolado and Jimeno (1997), Andrés et al. (1998) or Dolado et al. (2000) estimate VAR models. On the other hand, the structural modeling approach, in a partial equilibrium setting, has been followed by others, e.g. Andrés et al. (1990) or Blanchard et al. (1995).

³⁰1998 is the last year that data is available on the individual money supply series of the EMU countries.

³¹Pesaran and Shin (1995), Pesaran (1997), and Pesaran et al. (1996), show that the traditional ARDL estimation procedure can be applied even when the variables follow I(1) processes. (See also Henry, Karanassou, and Snower (2000) for an application of this approach and a discussion of its merits.)

(for no serial correlation, linearity, normality, homoskedasticity, and constancy of the parameters of interest) at conventional signi...cance levels.³² An important implication of the above methodology is that the long-run solution of the ARDL can be interpreted as the cointegrating vector of the variables involved (since an ARDL equation can be reparameterized as an error correction one).

Next, the following plausible restrictions were imposed on the model and accepted by the data: (i) constant returns to scale in production³³, (ii) the long-run elasticity of the labor force with respect to the working age population is unity, and (iii) absence of money illusion.³⁴ Finally, we estimated the equations of our macro model as a system, using three stages least squares (3SLS), to take into account potential endogeneity of the regressors and cross equation correlation.

Tables 2a and 2b present the restricted 3SLS estimates of each equation.³⁵ In the nominal wage equation, the explanatory variables have coe⊄cients of plausible magnitudes and signs, e.g. wages are inversely related to the unemployment rate and positively related to productivity. The price equation has a similar structure to the wage equation. Higher wages contribute to rise prices, but with some delay, and with a substantially smaller exect than prices on wages. Money supply exerts a greater in‡uence on prices than on wages in the short-run.

³²See Tables A1-A6 in Appendix B.

 $^{^{33}}$ The sum of the labor and capital coe Φ cients in our Cobb-Douglas production function is unity.

³⁴That is, the equations in our model are homogeneous of degree zero in all nominal variables. This restriction was imposed and accepted in the wage and price equations, and it automatically holds in all other equations since the real endogenous variables only depend on real variables.

³⁵Figures A2 in Appendix B picture the actual and ...tted values of the unemployment and in‡ation rates. The plots indicate that our model tracks the data very well.

(*) restricted coe $\$ cient for no money illusion in the long-run; $\$ denotes the dixerence operator; (+) coe $\$ cient is restricted so that the long-run elasticity with respect to $\$ Zt is unity.

In the labor force equation, the size of the labor force depends on its own past values (due to, say, monetary and psychic costs of entry and exit from labor force participation). It also depends negatively on the real wage, implying that the income exect dominates the substitution exect. This negative sign appears plausible for Spain, where income sharing among adult members of families is common, so that a rise in the wage of the main bread winner reduces the need for the spouse and children to seek work. Finally, the labor force depends inversely on the change in the unemployment rate. This may be interpreted as a type of discouraged worker exect: the greater the increase in the unemployment rate, the greater the level of long-term unemployment, ceteris paribus, and the greater the likelihood of exit from the labor force.

³⁶This reduces the in‡uence of the real wage channel, contained in the employment equation. ³⁷This argument is supported by the fact that the unemployment rate of the main bread winners is half that of the second earner one and one third that of the corresponding child earners. These di¤erences are largest in regions with the highest unemployment rates. Furthermore, data from the 1990 Household Budget Survey (Encuesta de Presupuestos Familiares, EPF) show that the net wage of the main bread winner was 1.390.091 pts. in that year, more than 40% higher than the one of the second earner (813.038 pts.) and twice the one of the child earners (684.700 pts.).

³⁸ From 1986 to 1990, the 1.7 million newly employed reduced unemployment only by 0.5 million.

(¤) restricted coe⊄cient for constant returns to scale.								

In the employment equation, labor demand depends, among other things, on the real wage, the capital stock and productivity³⁹. Restricting the long-run coe¢cient of the capital stock to unity is accepted by the data, implying constant returns to scale, which are also features in the production function. Employment also depends negatively on the real wage (representing the real wage channel, analyzed above), social security bene...ts per employee (reducing work exort by improving workers' outside options) and the indirect tax rate. The capital stock equation is analogous to the employment equation. Constant returns to scale is accepted: the long-run elasticity of capital stock with respect to labor can be restricted to one. Productivity has a positive in tuence on capital stock. Real wages, competitiveness, and the indirect tax rate have negative exects. Real money balances have a positive exect (working, say, via credit constraints and the real interest rate); they represent the real money balance channel analyzed above. Finally, the production function is standard, displaying constant returns to scale.

As noted, we endeavor to capture institutional and policy changes - henceforth

³⁹Note that employment also depends on the change in the labor force. A rationale is developed in Coles and Smith (1996), which argues that job matches depend more on new entrants to the labor force than on the level of the labor force, since ...rms' search primarily for new job applicants, rather than review the old ones. Thus the greater the increase in the labor force, the greater the number of new job applicants, and the greater the consequent number of matches.

called IPCs - through multiplicative dummy variables, as shown in Table 3. The introduction of unionized wage bargaining, beginning in 1973 (unions were not formally legalized till 1977), reduced wage persistence (as many of the Francoera employment regulations were scrapped) and employment persistence. As is well known, after the ...rst oil price shock Spanish production became less capital intensive. The Moncloa Pacts reduced domestic price persistence (by making prices more ‡exible) and increased the in‡uence of productivity swings on employment (by reducing ...rms' incentives to hoard labor). The ...rst wage of labor market reforms reduced wage and employment persistence. Spain's entry into the EEC in 1986 reduced wage and price persistence, and augmented the intuence of money on prices (via increased credibility of monetary policy). 40 Spain's entry into the EMS in 1989 reduced the exect of domestic prices on wages. The second wave of labor market reforms, announced in 1993, further reduced employment persistence. And ...nally, the third wave of reforms reduced wage persistence.

Table 3: Institutional and Policy Changes (IPCs)

- 1. Introduction of unionized wage bargaining: $W_{t_i,1}^{74}$ and $N_{t_i,1}^{74}$

 7. Second wave of labor market reforms: N_{ti1} 18. Third wave of labor market reforms: W_{ti1} 19

In this way our structural model of the Spanish economy endeavors to capture the interplay between macro shocks and lagged adjustment processes that are central to our analysis of the intation-unemployment tradeox, as well as the in tuence of institutional and policy changes on this tradeo ⁴¹

5. The Spanish Phillips curve

In the context of the empirical model above, given by the restricted 3SLS estimates, we now assess the slope of the long-run Phillips curve for Spain. We then examine how this tradeox was axected by institutional and policy changes.

⁴⁰M_t⁹⁴ aims to serve a similar purpose with regard to central bank independence.

⁴¹As the ...gures in Appendix B show, our model ...ts the data closely.

5.1. The Long-Run In‡ation-Unemployment Trade-o¤

To derive the slope of the long-run Phillips curve, we begin with a change in the growth rate of the money supply and simulate the associated changes in the long-run in‡ation and unemployment rates. The change in money growth may be interpreted as realization of the stochastic process generating the money growth rates, and thus our analysis is not subject to the Lucas critique. In particular, the money supply may be treated as an I(2) variable, 42 so that changes in the money growth rate are permanent. Since our empirical model is linear and thus the implied Phillips curve is linear as well, the size of the money growth change clearly makes no di¤erence to our estimated slope of the long-run Phillips curve. We let our initial money growth rate be 15% and our ...nal one be 5%. These values were derived by estimating the Kernel density function for the growth rate of the money supply (along the same lines as Bianchi and Zoega (1998), for example). 43

For the initial and ...nal money growth rates above, we let all the endogenous variables in our system converge to their long-run steady state growth rates, given the dummy variables that obtain at the end of our sample period. We thereby ...nd the change in the long-run in‡ation and unemployment rates associated with the change in the money growth rate, enabling us to derive the slope of the long-run Phillips curve at the end of our sample period.⁴⁴

The simulation exercise indicates that the above 10% reduction in money growth leads to a permanent increase of 3.70% in the unemployment rate, along with a permanent decrease of 10% in the in‡ation rate. Thus our model implies that the slope of the Spanish long-run Phillips curve is $d\%=du=\frac{1}{1}$ 2:7 (to the nearest two signi...cant digits) at the end of our sample period.⁴⁵

Of course this estimate of the slope pertains only to the range of observed variations in the in‡ation and unemployment rates. It is not permissible to extrapolate outside this observed range. Indeed, there are good theoretical reasons (lying beyond the scope of our theoretical model above) to believe that the long-run Phillips is nonlinear over a wider range and that the slope may turn vertical or even positive when the long-run in‡ation rate is su¢ciently high.

⁴²The Dickey-Fuller (DF) and Phillips Peron (PP) tests indicate that we cannot reject the I(2) hypothesis for the money supply. In particular, for ΦM_t we have DF= $_i$ 0:26 and PP= $_i$:41; the 5% critical value is $_i$ 2:95: (For $\Phi^2 M_t$ the DF and PP tests are $_i$ 4:91 and $_i$ 7:96; respectively.) ⁴³The results on this estimation are reported in Appendix C.

⁴⁴Since the model is linear, the evolution of the exogenous variables has no in‡uence on the slope of the long-run Phillips curve. Thus these exogenous variables can be set to zero in the simulation exercise.

⁴⁵The intuence of previous institutional and policy changes is examined below.

5.2. The In‡uence of Institutional and Policy Changes on the Long-Run Phillips Curve

In our model, as we have seen, some of the institutional and policy changes (captured by the dummy variables above) axect the labor market adjustment processes, and these processes - interacting with money growth - axect the slope of the long-run Phillips curve. We now assess the magnitude and signi...cance of this in tuence.

In the absence of all IPCs - at the beginning of our sample period - we ...nd that the slope of the long-run Phillips curve is $S_n = \frac{1}{i}$ 1:89 (where the subscript n stands for "no IPC"). This is the base-run case.

Next, we add the ...rst IPC to the base run, and we obtain the associated long-run Phillips curve slope.⁴⁶. We call this slope S_1 . We derive the contribution of ...rst IPC (S_1) by subtracting S_n from S_1 : $S_1 = S_1$ i S_n .

Analogously, we add the second IPC to the previous system, and evaluate the slope of the associated long-run Phillips curve in the presence of the ...rst and second IPCs, to be called S_2 . The contribution of IPC 2 is then measured as $S_{^2} = S_2$; S_1 . Along these lines, we evaluate the individual contribution of each IPC to the long-run Phillips curve slope. The results are given in Table 4. The top section of the table shows the in‡uence of a 10 percentage points decrease in money growth (Φ M) on unemployment (Φ u) and the slope of the long-run Phillips curve. The bottom section gives the individual contributions of each IPC to the slope ($S_{^{^{\prime}}}$) and the percentage di¤erence (%) in the slope implied by each IPC.

Observe that the IPCs which appear to have had the greatest impact are the introduction of the Moncloa Pacts and entry into the EEC and EMS. Our calculations show that these changes all made the Spanish long-run Phillips curve steeper.

⁴⁶Speci...cally, this is the slope in the presence of IPC 1 but in the absence of all other IPCs. After including the ...rst IPC, we reimpose on the macro system the restrictions to ensure no money illusion and constant returns to scale.

⁴⁷For example, entry into the EEC shifts the slope from -2.28 to -2.51 (in the top part of the table), which corresponds to a di¤erence of -0.23 percentage points that makes the slope 10.1% steeper (in the bottom part of the table).

Table 4: The long-run Phillips curve slope.					
Unemployment rate response to a 10 %points decrease	in ¢M

(%) percentage dixerence with respect to the case without any of the IPCs considered.					

5.3. Monte Carlo Simulations

We now examine whether our point estimates of the long-run Phillips curve slope are signi...cantly di¤erent from in...nity. Accordingly, we conduct Monte Carlo experiments, each of which consists of 1000 replications. In each replication (i), a vector of error terms $t^{(i)} = t^{(i)} t^{(i)}$

 $^{^{48}}$ We used the normal distribution because the assumption of normality is valid in the estimated system of equations. Thus " $_t$ » N (0;), where is the variance-covariance matrix of the estimated model.

on the newly estimated system. In this way, each replication (i) yielded a set of measures for the cumulative impact of IPCs on the long-run Phillips curve slope: $x_i = S_n^{(i)}; S_1^{(i)}; S_2^{(i)}; S_3^{(i)}; S_4^{(i)}; S_5^{(i)}; S_6^{(i)}; S_7^{(i)}; S_8^{(i)}$. We grouped the values of each generated series x_i into class intervals of 0.5 units. In Table 5 we present the percentage count of slopes within speci...c class intervals. For example, in the presence of all IPCs, the probability that the long-run Phillips curve slope is below -50 is 1.3%. Using as a cut-ox point a 2% count, there is no class interval below [-6,-5.5) or above [-1,-0.5) that contains at least 2% of the values of each x_i . So in Table 5 we also give the probability that the long-run Phillips curve slope is greater than -6.0 and smaller that -0.5.

Observe that in the absence of all IPCs the probability that the slope of the Phillips curve (S_n) is in the [-6, -0.5) interval is 77.7%. The Phillips curve slope remains more or less una α ected by the introduction of unionized wage bargaining and the occurrence of the oil price shock (see columns S_1 and S_2 ; respectively, in Table 5). However, when the institutional changes associated with the Moncloa Pacts are introduced, the Phillips curve slope becomes steeper (column S_3 in Table 5). In this case the probability that the slope lies between -6 and -0.5 drops to 72.3%. The Phillips curve slope does not change much when the ...rst wave of labor market reforms takes place (column S_4 in Table 5). But with the entry into the EEC the probability that the slope lies in the [-6, -0.5) interval further decreases to 67.6%, thus the Phillips curve gets steeper (column S_5 in Table 5). Finally, the entry into the EMS, ⁴⁹ and the second and third waves of labor market reforms do not appear to have a signi...cant impact on the Phillips curve slope (column S_6 ; S_7 ; and S_8 in Table 5).

Table 5: Monte Carlo simulations, 1000 replications										
1	probability (%) that the PC slope is within a specic interval									
	S _n	S ₁	S ₂	S ₃	S ₄	S_5	S ₆	S ₇	S ₈

6. Conclusions

This paper has provided a theoretical rationale for a long-run tradeox between intation and unemployment due to the interplay between money growth and

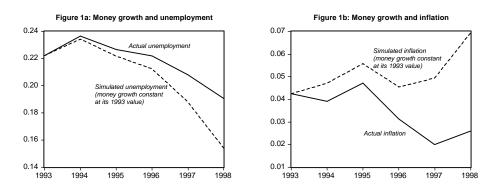

⁴⁹The result concerning EMS contrasts with our ...nding in Table 4.

nominal frictions. In this context we have seen that the absence of money illusion and money neutrality does not prevent changes in money growth from having long-run exects on unemployment (as well as in‡ation, of course). Thereby our analysis avoids the counterfactual prediction of the NAIRU theory that in‡ation falls without limit when unemployment is high.

Our analysis suggests a signi...cant role for monetary policy in combating Spanish unemployment in the long run. This role, however, has been reduced somewhat through successive policy changes, particularly the introduction of the Moncloa Pacts and Spain's entry into the EEC and possibly the EMS.

Our empirical model yields a point estimate of -1.89 for the slope of the Spanish long-run Phillips curve at the beginning of our sample period (so that a 10% decrease in money growth leads to a permanent rise in unemployment by 5.3 percentage points) and a point estimate of -2.70 at the end of our sample period (so that a 10% decrease in money growth leads to a permanent rise in unemployment by 3.7 percentage points). Our Kernel density analysis captures two broad money growth regimes, one at 15% (predominantly at the beginning of the sample period) and one at 5% (predominantly at the end). In short, our analysis suggests that this policy regime change had a pronounced exect on Spain's long-run employment rate.

Not surprisingly, the short- and medium-run exects on unemployment may be even more powerful. For instance, Spain experienced a precipitate fall in money growth over the 1990s, largely in response to the convergence criteria of the Maastricht Treaty (signed in February 1992), Spain's EMS crisis (from September 1992 to August 1993), and the independence of the Bank of Spain (granted in June 1994). In the context of our empirical model, we can ask how much of the rise in Spanish unemployment since 1993 can be accounted for by the experienced changes in money growth. Although it is important to emphasize that our empirical model is merely illustrative, Figures 1 nevertheless tell an interesting tale.

Figures 1: Unemployment and In‡ation Exects Attributable to Monetary Policy

Figure 1a gives the trajectory of the actual unemployment rate vis-a-vis the one the unemployment rate would have followed, in our model, if money growth had remained constant at its 1993 rate. The di¤erence between the two trajectories stands for the rise in unemployment, through time, that is attributable to the fall in money growth. Along the same lines, Figure 1b depicts the trajectory of actual in‡ation against the one the simulated in‡ation rate under money growth ...xed at its 1993 rate, so that the di¤erence stands for the fall in in‡ation, through time, that is attributable to the decline in money growth. In this simple accounting exercise, we see that, by 1998, the contractionary monetary policy accounts for a rise in the Spanish unemployment rate of about 4 percentage points and a fall in the in‡ation rate of also about 4 percentage points. In short, our model suggests that monetary policy has had a very substantial and prolonged e¤ect on unemployment (and of course in‡ation). Our empirical analysis of Spain's longrun in‡ation-unemployment tradeo¤ indicates that some of this unemployment e¤ect is permanent.

APPENDICES

Appendix A: An Overview of In‡ation and Unemployment in Spain

The story of the Spanish economy over the past 25 years is one of declining in‡ation and persistent unemployment, as shown in Figures A1 and Figure 3a in the text. The rate of in‡ation has gradually declined from 24.5% in 1977 to 1.8% in 1998, permitting Spain to join the EMU in 1999. The unemployment rate started low - below 5% until 1976 - but reached more than 21% in 1985. After hovering near this peak for another decade, it has since fallen to less than 15%.

Figure A1. Inflation and unemployment rate. Spain. 1966-1998.

Within this broad picture, we can distinguish ...ve di¤erent macroeconomic periods relevant to the Spanish Phillips curve.

The Period 1969-1977

From 1969 to 1974, Spain experienced a very strong expansion, with GDP growing at an annual rate of 6.6%. 1973 was the ...rst year in the postwar period when in ‡ation exceeded 10%, primarily on account of intense domestic demand pressure. In the following years, Spain had to deal with two severe macroeconomic shocks. One was the ...rst oil price shock, which had a pronounced exect on in ation and unemployment since Spanish industry was heavily dependent on oil imports. The other was the advent of unions in collective wage bargaining. Although unions were not legalized until 1977, their de facto in tuence was asserting itself already in 1973. The immediate implication in the period 1973-77 was a wage-price spiral, in which unions pushed up wages succiently to permit real wage growth after taking past in tation into account, while ... rms raised prices at an accelerating rate in order to recover their margins. This spiral was aggravated through accommodating macroeconomic policies. As a result, in tation rose above 15% during the period 1974-76 and reached 24.5% in 1977. However, the exects of the above shocks on unemployment were delayed; unemployment remained low, as shown in Figure A1 and Figure 3a.

The Period 1978-1985

This period featured the following further shocks. First, tight monetary policy was implemented in 1978 to control in accordance with the Moncloa Pacts 50.

 $^{^{50}}$ These pacts consisted of a set of policy agreements between the government, ...rms and unions in response to the economic crisis. On the one hand, there was a very restrictive monetary policy;

Next, the second oil price shock occurred in 1979. Together, these shocks reduced consumption, investment, and employment. As a consequence of the Moncloa Pacts, an incomes policy was implemented between 1978 and 1986, whereby the government set an in‡ation target, the unions agreed to accept moderation in wage increases, and ...rms agreed to price moderation.

In 1984 the government began a ...rst wave of labor market reform by introducing ...xed-term contracts to increase labor market ‡exibility and stimulate job creation. As a result temporary employment grew to one third of total employment over the second half of the 1980s.

As Figures A1 and 3a indicate, in tation came down during this period, but the unemployment rate rose dramatically, as a consequence of the lagged exects of the 1973-77 shocks as well as the 1978-1985 shocks.

The Period 1986-1990

Spain joined the EEC in 1986, and the resulting need for international competitiveness in what were previously highly protected product markets put downward pressure on wages and prices. Monetary policy was relaxed in 1986 and 1987, in view of the previous fall in in‡ation. These developments, together with the lagged exects of the labor market reforms of 1984, led to a sharp increase in employment⁵¹. GDP grew at a 4.5% annual rate, stoked by strong domestic demand. To prevent a resurgence of high in‡ation, monetary policies were tightened in the late 1980s, a move reinforced by Spain's entry into the EMS in 1989.

The upshot of these developments was that the unemployment rate fell from 21.5% in 1985 to 16.3% in 1990, whereas in ation remained tat (the intation rate, measured by the GDP detator, was at 7.7% in 1985 and 7.3% in 1990).

The Period 1991-2000

A rise in household indebtedness, the Iraqi war of 1991, the upward pressure on interest rates due to German uni...cation, and the EMS crisis of 1992 and 1993 together pushed the Spanish economy into a short-lived but deep recession. The unemployment rate rose from 15.9% in 1990 to 23.7% in 1994. This recession, together with the tight monetary policy implemented in accordance with the Maastricht Treaty signed in 1991, led to a decline in in‡ation from 7.3% in 1990 to 4.0% in 1994.

on the other, there were various structural measures, especially tax reform, incomes policy, and measures to promote competition, such as those in the ...nancial market. The restrictive monetary policy was implemented right away; the structural policies took several years to apply.

⁵¹Whereas temporary contracts were a rarity before 1984, the ratio of ...xed-term employment to dependent employment rose to 15.6% in 1987 (...rst year with o⊄cial data), and further to 32.2% in 1991.

In 1994 the Spanish government implemented a second wave of labor market reform⁵², and the Central Bank became independent, with a mandate to focus exclusively on in‡ation control. In 1997 there followed a third reform wave, in which ...ring costs on permanent contracts were reduced, thereby partially reversing the trend towards temporary employment⁵³.

These two labor market reforms played an important role in containing real wage growth and this in‡uence, along with a new cyclical upturn, provided a strong stimulus to employment in the second half of the 1990s. In years 1995-99, the annual growth rate of GDP reached 3.5% with an annual increase of 3.3% in employment and around 1.8 million jobs created.

These developments were reinforced by the monetary policy run-up to Spain's EMU entry in 1999, involving a sharp reduction in interest rates after 1995. In an attempt to keep in‡ation under control nevertheless, the government supplemented its labor market reforms by opening its product markets to foreign competition. Whereas this involved mainly the industrial sector in the second half of the 1980s, in the 1990s it included the service sector, particularly the ...nancial, transport, communication and telecommunication sectors. Several important public companies were privatized, which helped reduce the public-sector de...cit. As a result, the pronounced increase in employment in the second half of the 1990s was accompanied by a reduction in in‡ation. However, the labor force expanded and thus Spain's unemployment rate responded only moderately; by the end of the 1990s, it was still above 15%.

⁵²This second wave was a response to the ...rst. The main ...xed-term contract in the 1984 reform was the 'employment promotion contract,' which was used heavily by employers to cover both temporary and permanent tasks, and it gave Spain the highest rate of temporary employment in the EU. Thus, in the second wave of labor market reform of 1994, the government tried to restrict the use of this contract by attempting substitute it for other temporary contracts such as the 'contract per task or service' and the 'contract for launching new activities'. These were originally targeted towards some groups of hard-to-place workers, but in fact they were used in the same way as the previous contract. As a result, the third wave of reform in 1997 was implemented to favor permanent contracts.

⁵³The share of temporary employment on total dependent employment had reached 33.7% in 1994, remained at 33.6% in 1997, and reduced to 32.1% in 2000.
