

Stratigraphic distribution of Aphidfauna (*Hom.*) in Eastern Andalusian Mountains (South Spain)

Asish K. Ghosh¹ and Juan M. Nieto Nafría²

1. Zoological Survey of India. New Alipur. Calcutta, 700053 (West Bengal, India)

2. Departamento de Biología Animal. Universidad de León. 24071 León (Spain)

Key words: Andalusian; *Aphidoidea*; frequency of occurrence; host associations; vertical distribution.

Abstract. A total of 148 aphid species belonging to 69 genera and 7 subfamilies collected over last 40 years in Eastern Andalusian mountains has been analyzed with regard to their vertical distribution pattern, percentage composition at generic and specific level with regard to the total fauna at each altitudinal gradient, rarity and abundance and extent of floral association. Comparison has been made with Eastern Himalayan fauna in India showing some striking similarities and also characteristic differential features.

Resumen. *Distribución altitudinal de la afidofauna (Hom.) de las montañas orientales de Andalucía (sur de España).* Denominamos en el presente estudio Montañas orientales de Andalucía los macizos montañosos situados en el oriente andaluz con más de dos mil metros de altura máxima y que reciben una precipitación anual superior a los 400 mm. De la mayoría de ellos (Sierras: Nevada, Mágina y de Cazorla, en las provincias de Granada y Jaén) se poseen suficientes datos afidofaunísticos (ciento cuarenta y ocho especies pertenecientes a sesenta y nueve géneros y siete subfamilias) para analizar la distribución altitudinal de los distintos grupos taxonómicos, relacionándola con otros factores ambientales. Se han comparado los resultados obtenidos con los correspondientes de la parte oriental del Himalaya (India y Bután), observándose notables semejanzas, junto a diferencias relacionadas con el alejamiento biogeográfico de ambas zonas de montaña.

Introduction

Andalusian is the most meridional Spanish region in the Iberian Peninsula (Figura 1). It lies from East to West and has extension of 87.268 km².

Eastern Andalusian is a very hilly region with several mountains massifs that overpass 2000 m. Some of them (c.f Sierras de Baza, de los Filabres, de María) are particularly dry, with less than 400 mm rain per year. the other ones, though with some differences between them, received more than 600 mm (Bosque Mau-rel, 1991; Ortego Alba, 1991).

We have already aphid-faunistic data from the last ones, particularly from: Sierra Nevada, Sierra de Cazorla y Sierra Mágina (Figura. 1). For simplicity reason, in this article we will refer to these ones as Eastern Andalusian Mountains.

The aphid fauna of Eastern Andalusian Mountains have been surveyed by Mimeur (1936), Remaudière (1959, collections made by H. Janetschek and W. Steiner in Sierra Nevada en 1954), Notario *et al.* (1984), Gutiérrez Alaiz *et al.* (1985), Nieto Nafria *et al.* (1986), Meliá (1986), Mier Durante & Nieto Nafria (1988) and

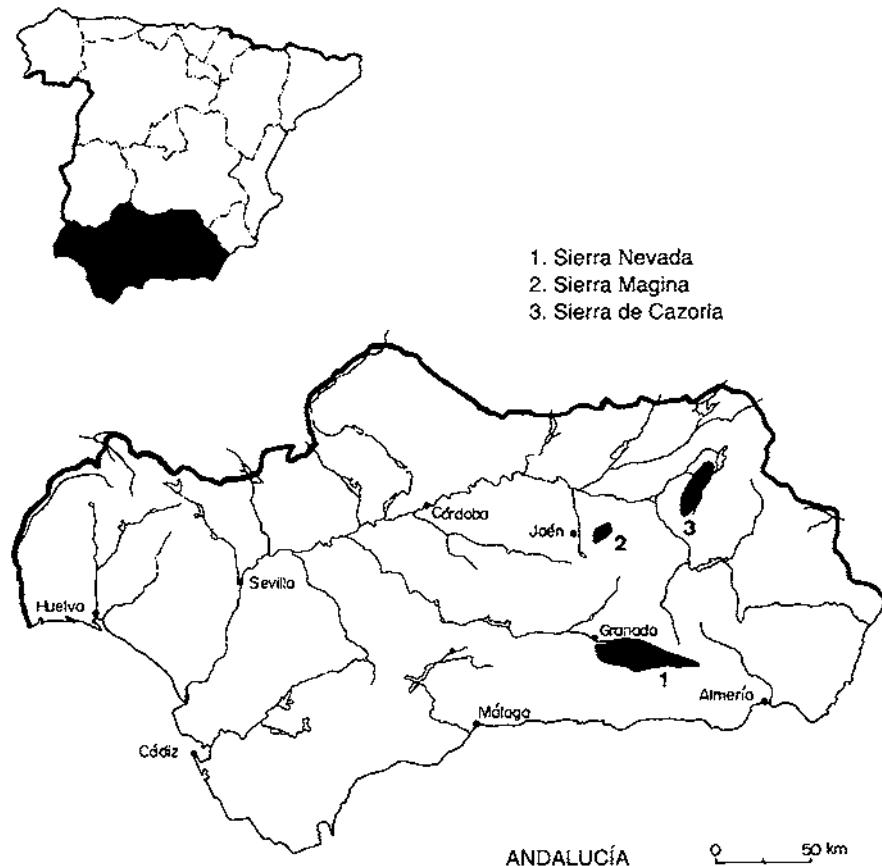

Figure 1. Map showing Andalusian region with Eastern Andalusian Mountains (shaded); inset, map of Spain showing Andalusia (shaded).

Nieto Nafría *et al.* (1990), revealing a total of 148 species belonging to 69 genera and 7 subfamilies (Table 1); this represents approximately 30% of the total Spanish aphid-fauna. The distribution of these species obviously depend on climatic conditions, vegetation and local dispersal pattern. In the present work an effort has been made to analyze the available aphid records from different locales (a total of 41) of Eastern Andalusian Mountains region with regard to their vertical distribution pattern, percentage composition at generic and specific levels and rarity and abundance.

Material and methods

Aphid material collected during last 40 years from 41 localities located between c 500 m to 3500 m were identified by the authors of the respective articles. The most part of the collections were made by hand from the affected part of the host plant besides by sweeping net and unidentified host plant-parts were preserved in herbaria and later identified by scientist on the Botany, Department of Vegetal Biology of the University of León. All collections were preserved in 70% alcohol and numbered. No trap material has been used for the present study.

These data were systematically collated and analyzed with regard to the subfamily positions, generic and specific taxonomy and host plant associations. The entire collections records were then analyzed with relation to the subfamilies *Pemphiginae*, *Anoeciinae*, *Thelaxinae*, *Chaitophorinae*, *Drepanosiphinae* and *Lachninae*. Percentage composition of the total aphid-fauna with regard to altitudinal gradient, both for the genera and the species under each of the subfamilies has also been analyzed to determine the factors of dominance. The major host associations at subfamily level were analyzed to determine the correlation of this phytophagous group of insects with cultivated or natural vegetation at different gradient level.

An alphabetical list of localities from the collection records and their altitude is given in table 2. It may be noted that majority of the collection localities come under Granada province (Sierra Nevada) except a few from Jaen province (Sierra de Cazorla and Sierra Mágina).

Results

The analysis shows that the *Aphidinae* forms the single largest group of taxa in the Eastern Andalusian Mountains represented by 40 genera and 97 species (Table 1), with 58% of the total genera and 65.5% of the total species known in the region. When analyzed at different gradient level, the aphidine genera and species represent: 62.2% and 69% in gradient I (500 to 1000 m), 68.5% and 69.5% in gradient II (1000 to 1500 m), 73.7% and 64% in gradient III (1500 to 2000 m), 66.7% for both genera and species in gradient IV (2000 to 2500 m), 42.9% for both genera and

species in gradient V (2500 to 3000 m) and 71.4% for both genera and species in gradient VI (3000 to 3500 m), with regard to the total genera and species in each gradient respectively. Only 24 out of a total of 97 aphidine species have been recorded above c 2000 m.

Of the total Aphidid taxa, the genus *Aphis* Linnaeus has a wide spectrum of species (29 out of 148) mostly recorded between c 500 m to 1500 m and only 4 of the 29 species have been recorded above c 1500 m; of these, *Aphis fabae* Scopoli seems to be abundant and to have exploited maximum altitudinal range and number of floral species while *Aphis gossypii* Glover has only been recorded once by a vagrant alate at the highest stratum (Remaudière, 1959).

Most of the aphidine genera is represented by one or two species while for *Acyrthosiphon* Mordvilko (3 species), *Brachycaudus* Van der Goot (3 species), *Coloradoa* Wilson (3 species), *Macrosiphoniella* Del Guercio (5 species), *Macrosiphum* Passerini (3 species) and *Uroleucon* Mordvilko (7 species) more species have been noted. Needless to mention that the aphidine taxa show the widest host plant spectrum in the entire region of study.

The subfamily *Pemphiginae* (11 genera) shows more generic dominance than *Drepanosiphinae* (9 genera) and *Lachninae* (6 genera) but is represented by only 12 species of which two species have been recorded above c 2000 m by vagrants. Host association remain mostly restricted to *Hordeum*, *Pistacia*, *Scirpus* and *Ulmus spp.* Percentage composition of genera and species of *Pemphiginae* with relation to the total aphid taxa at each gradient level has been given in table 3.

The subfamilies *Anoeciinae* and *Thelaxinae* each is obviously represented by a single genus and a species and as such form insignificant component of Eastern Andalusian Mountain fauna; it is however interesting to note that *Anoecia corni* (Fabricius) has only been recorded above c 2500 m from *Reseda complicata* (vagrants?) by Remaudière (1959) but *Thelaxes suberi* (Del Guercio) has been recorded a number of times between c 500 m to 1500 m from *Quercus spp.* (*Q. rotundifolia* and *Q. pyrenaica*) and once each on an unidentified gramine at c 2960 m and 3380 m.

The subfamily *Chaitophorinae* is represented by two genera and 5 species of which the genus *Chaitophorus* Koch occupies predominant position; of the 5 species only one, *C. gomesi* Ilharco has being noted above c 1500 m, the usual hosts for *Chaitophorinae* being available below c 1500 m (*Acer*, *Populus*, *Salix spp.*). The percentage composition of Chaitophorids is shown in table 3 and the vertical distribution has been observed in table 2.

The subfamilies *Drepanosiphinae* and *Lachninae* each is represented by 16 species (Table 2). While in *Drepanosiphinae* only 2 out of 16 species (9 genera) have been noted above c 2000 m, at least 50% of the Lachnids species (under 6 genera) occurred also above c 2000 m and in one case *Eulachnus agilis* (Kaltenbach) was recorded at c 2820 m on *Pinus* in Sierra Nevada. Percentage composition for group of genera and species for each of these two subfamilies have been given in table 3. The occurrence of Lachnids above c 2000 m can be correlated with the preponderance of appropriate conifer hosts at that level (*Pinus spp.*).

Rarity and abundance

Most of the species of aphids in the region seem to be rare in occurrence but all the year round survey may invariably yield a better result. On the basis on random sampling done during five major survey periods, *Aphis fabae* Scopoli, seems to be most frequent in occurrence followed by *Aphis craccivora* Koch, *Brachycaudus helichrysi* (Kaltenbach), *Myzus persicae* (Sulzer), *Macrosiphum rosae* (Linnaeus) and *Uroleucon sonchi* (Linnaeus), all other species have been collected only once to four times. The preponderance of these six common aphid species can be attributed to their ability to feed on a number of host plants or easy availability of cultivated hosts (e.g. *Rosa* for *Macrosiphum rosae*) at different locations.

Discussion

Some of the species, such as *Pemphigus spirothecae*, *Myzocallis castanicola*, *Chaithophorus leucomelas*, *C. salijaponicus niger*, *Brevicoryne brassicae*, *Diuraphis noxia*, *Rhopalosiphum insertum*, *Schizaphis graminum* and *Uroleucon (Uromelan) jaceae*, have not been recorded at certain altitudinal levels, where their presence may be possible due to their relatively abundance in Spain and to the presence of their host plants. There may be a small presence of these species at different levels, which could be detected by a more detailed sampling.

Either way, it is our opinion that these possible changes could not modify the general idea of the altitudinal distribution in the aphids subfamilies at Eastern Andalusian Mountains (Ghosh *et. al.* in press).

The aphid fauna in Eastern Andalusian Mountains shows a positive assemblage at lower altitude between *c* 500 to *c* 2000 m; the vegetation cover being more favorable such occurrence appears rational. However, 148 species recorded hearing appear to be largely restricted to 125 species of flora, both cultivated and wild. Of these, 14 species of flora have so far been used by *Aphis fabae* Scopoli, while *Aphis craccivora* Koch follows with seven host species in the region.

As regards frequency of distribution of aphid taxa, a similarity can be observed between Eastern Himalaya in India and Eastern Andalusian Mountains, where maximum concentration of aphidine species is noted between *c* 600 m to 2400 m (73 to 88%) [Ghosh & Raychaudhuri, 1977]. In terms of percentage composition Aphidine species comprise 66.8% in Eastern Himalaya as against 65.5% in Eastern Andalusian Mountains. The Drepanosiphine fauna in Eastern Himalaya represent 8.6% of the total aphid genera and 13% of the total aphid species as against 10% and 10.8% in Eastern Andalusian Mountains, respectively; the maximum number of the Drepanosiphine aphid occur between *c* 1200-*c* 2400 m in Eastern Himalaya while such concentration is noted at lower altitude between *c* 500 to 1500 m in Eastern Andalusian. The Pemphigine fauna shows preference to higher altitudes in Himalaya (*c* 1201 to 1800 m) in contrast to the fauna in Andalusian region (*c* 500 to 1000 m). Lachnid fauna has in general more representation in the Palearctic

Region and the occurrence of 16 species in Eastern Andalusian Mountains, with maximum concentration between c 1000 to 2000 m represent double the number of Lachnid species in Eastern Himalaya largely occurring between c 1800 to 2400 m. The edaphic factors and vegetation being different in these two widely separated geographical areas, the level of differences appears logical.

The present study indicates that a proper management strategy for control of aphid pest both on cultivated plants and natural vegetation could be formulated keeping in view the vertical distribution pattern, availability of obligatory or alternate host plants and other related biological parameters.

Acknowledgments

The authors are thankful to Spanish Ministerio de Educación y Ciencia (D.G. de Investigación Científica y Técnica) for supporting the current research program (SAB/93-0130). The authors also acknowledges with thanks the research grants «DGICYT PB 1987-0397, Fauna Ibérica I» and «DGICYT PB 1989-0081, Fauna Ibérica II» of the Spanish Government. Thanks are also due to M. Enrique Ortega for preparation of the map.
