Introduction

The disease

West Nile virus (WNV) is a mosquito-borne Flavivirus belonging to the Japanese encephalitis antigenic complex, within the family Flaviviridae and it can cause West Nile Fever (WNF). Its natural cycle involves transmission between ornithophilic mosquitoes, mainly Culex species, and birds, which act as amplifying hosts. Mammalian species, including humans and horses, may get infected, but they do not seem to able to sustain the transmission cycle (see figure 2). The WNF is considered a notifiable disease by the OIE and the EU, and it’s an emerging zoonosis in many parts of the world.

Situation of the WNF in Spain and Catalonia

The WNF is present in the southern of Spain (see figure 2) since 2010. In Catalonia it has never been found WNV active infection in horses but virus belonging to Japanese encephalitis complex are circulating in equines. However, specific antibodies against WNV have been detected in migratory birds making possible the emergence of the disease in Catalonia.

Material and methods

- Revision of WNV ecological surveillance results from 2007 until 2013.
- Identification of regions (see figure 4) where:
  - Don’t have information about birds and have minimum apparent prevalence above 3%.
  - The sampling frequency is less than 1%. Also, regions with more than 25 samples taken were discarded.
  - The population of Culex mosquitoes (Culex pipiens and Aedes albopictus) could be important.
- Collaboration of 3 clinical veterinarians, visit of 3 equine farms per region and getting 3 samples for each farm (9 samples in total per region).
- Analysis of the samples with competitive ELISA (IgG) by CreSa. Analysis of positive samples with IgM capture ELISA by CreSa and confirmation of these with seroneutralization (SNT) by Veterinary Central Laboratory of Algete.

Results and discussion

Sampling

Only one sample (from Tarragonàs) has specific antibodies against WNV (positive to SNT, see figure 5). This horse has been, two months before, in Alcàzar de San Juan (Castella La Manxa) where there is a very high risk of transmission of disease, making likely the contact between the virus and the horse in that area.

Surveys

The most important result of surveys has been to find a high percentage of veterinarians (44.4%) who don’t want to collaborate with the vigilance program. Some of reasons are:
- Lack of time due to their job demands.
- Lack of participation by the owners, because they haven’t got REGA code or because they are reticent to have anything to do with a zoonosis.
- No observation of compatible clinical signs or detection of positive animals in the professional practice.

Conclusions

The WNV was not detected in any of the horses of this regions, but it’s important to keep active and passive surveillance in different regions of Catalonia because the disease may appear at any time. However, virus belonging to Japanese encephalitis complex are still present. The main weak point of the program is the lack of cooperation from clinical equine veterinarians. It’s necessary to carry out measures to promote their participation.
