Design of a bacterial ghosts-based vaccine against Staphylococcus aureus

Maria Peña Romero
Bachelor’s degree in Biotechnology
Universitat Autònoma de Barcelona

1. Introduction
This poster is a Research Project Proposal for the design of a vaccine against Staphylococcus aureus. S. aureus is a gram-positive bacterium, the most common cause of nosocomial infections. It is also resistant to most of the antibiotics. The design of an effective vaccine would reduce the amount of infected people, specially in hospitals.

2. Hypothesis
Escherichia coli’s Bacterial Ghosts (BG) that express Fibrinectin-binding protein A (FnBPA) in their surface will generate effective immune response against S. aureus infections. Positive evidences were shown in a BG-based vaccine against Helicobacter pylori.

Why FnBPA?
- Fibrinectin binding protein A is a S. aureus protein which allows the bacterium to adhere to hosts and enter inside them, acting as a bridge.
- FnBPA is involved in adherence to mammalian cells and in the infective process.
- In Helicobacter pylori a BG-based vaccine had positive results using a protein with a 70% of identity with FnBPA. This was determined by a BLAST analysis.

Materials and Methods

Plasmid constructions
- pHS64FnBPA: 38 aminoacids of FnBPA were cloned into plasmid pH54. FnBPA was flanked between two ompA (outer membrane protein A) sequences. This allows the expression of the FnBPA in the E. coli outer membrane. This construction is under a P_{lac} promoter control.

pLySE: cassette with lysis E gene was cloned into plasmid pBBR1MCS5 with a replication origin and a gentamicin resistance. Its induction is under temperature regulation.

Vaccine production

1. E. coli is cultured in LB media at 28°C and transformed with pHS64FnBPA and pLySE plasmids by electroporation. CFUs are counted.
2. pHS64FnBPA induction adding 0.5 mM IPTG: ompA-FnBPA38-ompA insertion in E. coli outer membrane.
3. pLySE induction raising temperature to 42°C: tunnel formation.
4. Antibiotic addition to inactivate E. coli after transformation and after 1h, CFUs recount.
5. SDS-PAGE and Western Blot assay to determine if FnBPA is into the outer membrane.

Immunogenic assays

28 weeks-old females BALB/c mice were immunized via subcutaneous injection (15 ♀ for each group)

Conclusions
After first immunization, FnBPA specific Abs are expected to be detected in both sample injection and positive control in the two ELISA test. If there is no presence, the boost dose (half of the initial dose) is supposed to solve this problem. FnBPA-Abs presence in negative control should to be zero.

TCDD and TCD8 lymphocytes are also supposed to be detected in immunized mice using flow cytometry. The same response as in ELISA test has to be detected in negative control.
The CFUs concentration in the surveillance assay is supposed to kill the 80% of mice not immunized. Control and treated mice with the BGs carrying FnBPA are supposed to have higher surveillance rates than negative control. The best situation will be a 100% surveillance with the sample dose.

If this strategy works in mice it should be a good vaccine to be tested in human patients.
