NEUROBIOLOGICAL BASIS OF ANGER

Dániel Sámpedo Viana. Biology Degree. Universitat Autònoma de Barcelona

INTRODUCTION

Anger is a frequent destructive emotion that has an important role in society and the public health. But, do we know how anger structures in our brain? Do we know how we regulate such an important emotion?

OBJECTIVE

The main objective is to show the knowledge that we have about how anger work in the human brain through a literature review of the current status of this area of cognitive neuroscience.

CONTENT

The RAGE SYSTEM

A very efficient and effective way to study the structures involved in anger is by observing the rage system. Based on studies of brain stimulation it has been considered that the structures involved in the circuit of rage are:

- Amygdala
- Hypothalamus
- PAG (periaqueductal gray)

Rage circuit runs from the middle of the amygdala, through areas of the hypothalamus and down towards midbrain PAG.

The system is organized as a hierarchical structure such that aggression evoked by stimulation of the amygdala depend on the functional integrity of the medial hypothalamus and periaqueductal gray. However, the aggression evoked by stimulation of the medial hypothalamus does not depend on functional integrity of the amygdala but depend on the integrity of PAG.

REGULATION and ACTIVATION

Seeking and Rage system

The most common causes that generate anger are caused by irritation and frustration, like:

• Restriction of freedom
• Restriction of access to resources

"Frustration-agression hypothesis" suggests that the RAGE system must be anatomical and neurophysiologically linked to the SEEKING system.

Neurochemistry of Anger

• Serotonin (5-HT)

Experiments show that the function is different depending on what 5-HT receptor is activated:

• 5-HT1A: Suppress PAG ➔ NO ANGER
• 5-HT2C: Activate PAG ➔ ANGER!

• Substance P

Substance P works as a neurotransmitter and neuromodulator activating the hypothalamic receptor NK1 who promotes aggression and anger.
